

# Removal or Modification of Obsolete Dams in Georgia

A Handbook for Project Managers and Dam Owners

> The Georgia Aquatic Connectivity Team June 2020

# Table of Contents

| Why remove dams in Georgia?  | 4  |
|--|----|
| Introduction   | 5  |
| Step 1: Research the Dam   |    |
| Section 1.1 Getting Started  | 7  |
| Section 1.2 Determining the Current Dam Ownership  | 7  |
| Section 1.3 Physical Properties of the Dam   | 8  |
| Section 1.4 Public Infrastructure  |    |
| Section 1.5 Historical Significance of the Dam   |    |
| Section 1.6 Current Regulatory Status of the Dam: FERC, GA Safe Dams Program                       | 11 |
| Step 2: Research the River and Surrounding Landscape   |    |
| Section 2.1 Basic Description of the Resource  |    |
| Section 2.2 Water Quality  |    |
| Section 2.3 Wildlife Resources   |    |
| Section 2.4 Connectivity   |    |
| Section 2.5 Wetlands   |    |
| Section 2.6 Sediment   |    |
| Section 2.7 Federal Emergency Management Agency Flood Hazard                                       |    |
| Section 2.8 Historical Use of the River  |    |
| Section 2.9 Recreation/Public Safety   |    |
| Section 2.10 Ecosystem Services and Resilience   |    |
| Section 2.11 Economic Issues   | 22 |
| Step 3: Understanding the Regulatory Process for Obtaining a Permit for Removal of Dams in Georgia |    |
| Section 3.1 Federal Regulatory Authorities Overview  |    |
| Section 3.2 Army Corps of Engineers Permitting Overview  |    |
| Section 3.3 Individual vs. General Permits   |    |
| Section 3.4 State Regulatory Overview  | 26 |
| Step 4: Planning and Design of the Project   |    |
| Section 4.1 Identifying Consultants  |    |
| Section 4.2 Identifying Relevant Stakeholders  |    |
| Section 4.3 Evaluation of Project Alternatives   |    |
| Section 4.4 Stages of Project Design   | 30 |
| Step 5: Implementation/Deconstruction  |    |
| Section 5.1 Project Construction   |    |
| Section 5.2 Public Relations During Construction   |    |
| Step 6: Post-Removal Actions   | 27 |
| Section 6.1 Project Evaluation   |    |
| Section 6.2 Environmental Monitoring   |    |
| Looking Ahead  |    |
| References   |    |
| Case Studies   | 40 |
| Case Study 1: The Eagle & Phenix and City Mills Dams, Columbus, GA (2012)                          |    |
| Case Study 2: The Nature Conservancy, 3 Dams in Marion County (2020)                               |    |
| Case Study 3: White Dam, Athens, GA (2018)   | 50 |

**Acknowledgements:** The Georgia Aquatic Connectivity Team (GA ACT) was created in 2015 to bring together a wide range of partners to support removal of obsolete dams across the State. To learn about the process of dam removal, members of the GA ACT worked with the University of Georgia (UGA) on their removal of the White Dam in Athens, Georgia. In July 2018, an 88.5-foot long section of the dam was removed, reconnecting 29 kilometers of the Middle Oconee River, improving aquatic connectivity, while minimizing impacts to the historical significance of the dam. This Handbook, which captures lessons learned from that project and seeks to provide information to support future removals, was coordinated by the GA ACT Regulatory Subcommittee, in collaboration with multiple state and federal resource and regulatory agencies, conservation organizations, academics and dam owners. For information on the GA ACT and for continuing updates on dam removal in Georgia, please visit <u>ga-act.org</u>.

Project coordinators, Lisa Perras Gordon and Jay Shelton, would like to express their appreciation to Sara Gottlieb of The Nature Conservancy (TNC), and Kat Hoenke of the Southeast Aquatic Resource Program (SARP), for their leadership on the GA ACT. It is no small effort to bring together a diverse group of stakeholders and to provide a meaningful platform for collaboration, which they have successfully done with the creation and running of the GA ACT.

This Handbook would not be possible without the efforts of the authors, contributors and reviewers, who made time in their exceptionally busy professional lives to share their expertise and their organizations' knowledge, processes and resource information.

Jon Becker, U.S. Environmental Protection Agency Walter "Tripp" Boltin, U.S. Fish & Wildlife Service Richard Campbell, U.S. Fish & Wildlife Service Jamal Cooper, U.S. Environmental Protection Agency Molly Dawson, P.E., U.S. Department of Agriculture, Natural Resources Conservation Service Jennifer Dixon, MHP, GA Department of Natural Resources, Historic Preservation Division Lisa Perras Gordon, U.S. Environmental Protection Agency Sara Gottlieb, The Nature Conservancy Kat Hoenke, Southeast Aquatic Resource Partnership Dan Holliman, U.S. Environmental Protection Agency Hal Jones, U.S. Fish & Wildlife Service Peter Kalla, Ph.D., U.S. Environmental Protection Agency Chris Manganiello, Ph.D., Chattahoochee Riverkeeper Paula Marcinek, GA Department of Natural Resources, Wildlife Resources Division Patrick O'Rouke, Georgia Power Company Freya Sargent, The Nature Conservancy Jay Shelton, University of Georgia Eric Somerville, U.S. Environmental Protection Agency Carrie Straight, U.S. Fish & Wildlife Service Kevin Thames, U.S. Army Corps of Engineers Michele Wetherington, U.S. Environmental Protection Agency Tom Woosley, GA Department of Natural Resources, Environmental Protection Division

Special thanks to Diane K. Nardin for her editorial review, which significantly improved the readability of this Handbook. Special thanks to Ania Truszczynski, Ph.D., and Elizabeth Booth, Ph.D. of the Georgia Environmental Protection Division (GA EPD) for providing valuable review comments on the final draft.

#### Why remove obsolete dams in Georgia?

Obsolete dam removal offers many benefits for dam owners, communities, state and local economies, anglers, recreationists, wildlife populations, and the environment. Removing dams can improve:

- Maintenance costs: Dam owners may find the cost of removing a dam significantly lower than the cost of maintaining or repairing an aging structure that has outlasted its usefulness.
- Public safety: Each year, fatalities result when swimmers, kayakers, canoers or anglers get trapped in the hydraulics below low-head dams. Removing obsolete dams permanently eliminates this danger and, potentially, the associated liability for the dam owner.
- Fish populations: Dam removal can help restore Georgia's once thriving migratory fish runs that were a significant contributor to the cultural landscape and heritage of Native Americans and early settlers of the state. Shad, sturgeon, striped bass and many other species have been shown to quickly return to spawning grounds once barriers are removed providing an opportunity to return long lost cultural traditions.
- Recreation: When dams come down, safe recreation can be established for water trails, parks and greenways that support the local economy. According to the Outdoor Recreation Industry, over \$179 billion was spent on outdoor activities in 2018 in the South Atlantic region of the United States alone, resulting in more than \$10.6 billion in state and local tax revenues and more than 1.5 million jobs.
- Water quality: Restoring rivers and streams by removing dams can significantly improve water quality. Removal of dams often restores habitat for species endemic to Georgia, such as those that formerly thrived in shoals (the shallow, fast-moving areas of water on bedrock or cobble) long ago flooded by impounded waters (see insert.)

# **Did you know? GEORGIA SHOALS**

Flat Shoals Road, Hurricane Shoals Road, Cochran Shoals Park, Shoal Creek Park, Flat Shoals Elementary School and the town of North High Shoals are among the dozens of roads, towns, parks and buildings named after this river feature in Georgia. The ubiquitous use of the term may reflect the economic and cultural importance of this river feature to the early settlers and Native Americans before the era of dam building in the 20th century. (Marcinek, et al, 2005; Manganiello, 2014) Shallow, rocky shoals provided richly oxygenated water producing an abundance of fish and productive habitat for many aquatic species, including mussels indigenous to Georgia, the beautifully flowering Shoals Spiderlily (shown right) and the aptly named Shoal Bass. Restoration of rivers through removal of obsolete dams may restore shoal habitat and encourage restoration of these species and river features, which are important both historically and economically to Georgia.

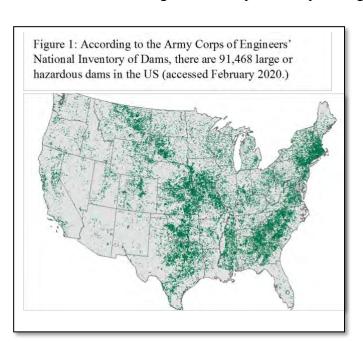

#### INTRODUCTION

Dams provide many useful functions across the country, including generating hydropower, supplying drinking water and providing recreation. However, removing or modifying obsolete dams – those that no longer serve any purpose - has emerged as a viable means of restoring connectivity for aquatic life in rivers and streams, enabling safe passage for river and stream recreation, and providing dam owners with a cost-effective option for addressing unsafe, aging infrastructure. According to American Rivers' database on dam removals, over 1,722 dams have been removed in the United States. In 2019 alone, 90 dams were removed reconnecting 973+ upstream river miles.

The purpose of this Handbook is to provide dam owners and project managers in Georgia with the information and resources needed to undertake a dam removal or modification project. All such projects have unique aspects and varying complexities, depending on the primary factors driving project initiation and permitting – whether it be restoration of aquatic life or water quality, improvement of public safety or cost reductions, and/or the protection of endangered species or historic or cultural sites. While many excellent sources of information on dam removal are available, this Handbook is specifically intended to address information gathering and the regulatory permitting process in Georgia. It provides direct links to the most-up-to-date information on relevant State resources and regulatory agencies.

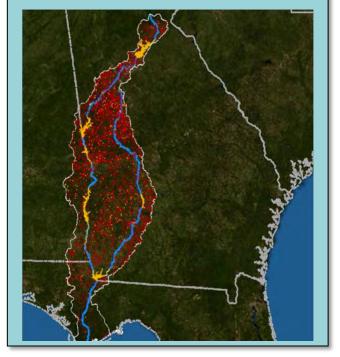

This Handbook provides information and references for a six-step approach to dam removal, encompassing information gathering, permitting, design and removal. Project managers and dam owners should note that moving from conception and planning to actual removal of a dam may not be a linear

process. Each of the steps may proceed at different speeds, with many occurring at the same time or in different order.

It is acknowledged that dam removal is a relatively new form of aquatic restoration in Georgia, and experienced consultants and engineers may not be familiar with the associated logistical challenges of these projects. To encourage successful implementation of dam removal projects in Georgia, it is important to work closely with the regulatory agencies and ensure that the contractor hired to remove the structure works closely with the consulting team designing the project. This will help to ensure that what is "on paper" can be implemented on the ground and in the water. This is important in terms of human safety, habitat considerations, cost and timing as we look ahead to successfully removing dams in Georgia. There are ample opportunities to remove obsolete dams that no longer serve a purpose and restore free flowing waters in the U.S. and in Georgia. Over 90,000 large and hazardous dams are identified in the U.S. Army Corps of Engineers' (Corps) National Inventory of Dams (NID) (see Figure 1)1. However, this list does not include small and medium sized dams, defined as those that do not meet the NID or Georgia Safe Dams Program's Category I or Category II dams (see below). These smaller dams do not fall under any regulatory program and are not tracked in any formal tracking system. The number of these dams is estimated to range from 2,000,000 to as many as 2,500,000 nationwide (Poff and Hart, 2002). Many of these smaller dams, such as those built to support the early mill economy, are considered obsolete and may no longer serve a functional purpose. (Graf, 1993, EPA, 2016)

Since 2010, the Southeast Aquatic Resource Partnership (SARP), researchers, and other conservation practitioners have worked to identify dams within the Southeastern United States that do not meet the criteria to be included in the NID. While the total number of dams in the Southeast is not known, over 137,000 dams have been identified within SARP's Comprehensive Southeast Aquatic Barrier Inventory. Of those, approximately 20 percent (or over 30,000) are in Georgia. Only a small fraction of these meet the definition to be regulated under the <u>Georgia Safe Dams Program</u>. As outlined in Step 3, to A remote sensing exercise identified 24,613 small, 736 medium and 13 large reservoirs in the Apalachicola-Chattahoochee-Flint river basin. Approximately 11,000 were dams on streams. Of those, only 1,129 meet the definition to be included in the Corps' National Inventory of Dams. (Ignatius & Stallins, 2011)

qualify as a regulated dam under this program, a dam must be 25 feet in height and/or impound 100-acre feet of water. Around 4,500 dams in the State fall into that category. Over 80 percent of those regulated dams were constructed of earthen material. For regulated dams with known construction dates, most were constructed in the 1960s (NID, 2019). The remaining dams are unregulated by state or federal programs.

#### DAMS IN GEORGIA

~30,000 DAMS CURRENTLY IDENTIFIED >4,500 REGULATED UNDER THE GEORGIA SAFE DAMS PROGRAM ~80% OF REGULATED DAMS ARE EARTHEN MOST REGULATED DAMS WERE CREATED PRIOR TO THE 1970'S

Source: SARP, 2019

In addition to the information provided in this Handbook, project managers and dam owners may find the following resources of value:

American Rivers' Removing Small Dams, A Basic Guide for Project Managers provides general information for project managers including project management and design, information on potential funding sources, and recommendations on community involvement.

<sup>&</sup>lt;sup>1</sup> The NID includes dams meeting one of the following criteria: 1) High hazard potential classification - loss of human life is likely if the dam fails, 2) Significant hazard potential classification - no probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or impact other concerns, 3) Equal or exceed 25 feet in height and exceed 15 acre-feet in storage, 4) Equal or exceed 50 acre-feet storage and exceed 6 feet in height.

- The Environmental Protection Agency's Frequently Asked Questions on Removal of Obsolete Dams provides information on water quality, Clean Water Act (CWA) permitting requirements, and EPArelated funding sources.
- ✤ A wide variety of other state-specific guides are also available with excellent resources, for instance Massachusetts, New York, Texas, and Vermont.

Please note that all permits and approvals must be obtained prior to any removal or modification of a dam in Georgia.

#### **STEP 1: RESEARCH THE DAM**

#### Section 1.1 Getting Started

The first step in beginning a dam removal project is to gather information about the dam. A significant amount of data and information can be collected upfront by the project manager or dam owner to save costs and time before beginning the permitting process or selecting an engineer to construct the project2. As noted throughout the document, the project manager or dam owner should keep an open line of communication with the Corps Project Manager. This communication will be critical in determining how much information is needed for the federal CWA permitting process. The information outlined below includes that which will be needed for permitting, as well as additional information needed to design the removal or conduct outreach. The amount of information needed for permitting and to have sufficient information for removing the dam will vary for each project. Not all information outlined below may be needed.

The dams name and address will be helpful for all subsequent steps. <u>Google Maps'</u> "Map" and "Satellite" views and <u>Google Earth</u> are excellent resources to help determine the physical address of the dam, or the closest address nearby, as well as the dam's latitude and longitude. SARP's <u>Southeast Aquatic Barrier</u> Prioritization Tool is also a great resource to help identify the exact location of a dam. Many dams have names that help to identify them: the dams removed on the Chattahoochee River in 2012, for example, had been known as the Eagle & Phoenix and the City Mills dams; the dam removed by UGA in 2018 was called Whitehall or White Dam.

#### Section 1.2 Determining the Current Dam Ownership

According to the Georgia Safe Dam Program (GA SDP), the "owner of a dam is considered to be anyone who owns any portion of the dam or appurtenant works of the dam. This is generally determined using county tax records. If these records indicate that [the owner's] property includes any part of the dam, [the property owner is] judged to be either an owner or partial owner of the dam." The rules that apply under the GA SDP, "...do not distinguish between the owner/operator of a dam" stating that, "[i]f your property does not include a portion of the dam, but you are an operator (such as by holding an easement, performing maintenance activities, controlling the spillways, etc.), you are also considered an owner."

The GA SDP notes that in Georgia, dams are owned by state or local governments, public utilities, and private individuals. Due in large part to the issue of multiple owners, it is difficult to provide exact

<sup>&</sup>lt;sup>2</sup> Note: The process of removing a dam is often called "construction," a term used throughout this Handbook to refer to active removal of the dam.

proportions of ownership categories. In many cases, a dam may be owned by multiple entities such as a private individual and a local government. In Georgia, as well as nationally, 60 to 70 percent of dams are considered privately owned. Around 30% of the regulated dams in Georgia are considered state owned. A majority of these state-owned dams are classified as flood control dams, many of which were designed and built by the U.S. Department of Agriculture, Natural Resources Conservation Service (NRCS) (formerly known as the Soil Conservation Service) to mitigate downstream flooding. These flood-control dams were built on private land and once constructed, the operation and maintenance of the dam was turned over to state and/or local government entities via easement agreements.

It is a common misconception that many of the regulated dams in the state and across the country are abandoned. In reality, only 2,900 dams out of over 90,000 dams in the NID are indicated as not having an owner (approximately 3%). That percentage is even smaller in Georgia, (for more info, see Section 1.6.1).

In addition to determining basic ownership of the dam, project managers will also need to determine:

- Who currently owns the property on either side of the dam?
- Who currently owns land below the dam that could be impacted by its removal?
- What is the current ownership of homes/lands on impounded waters that could be impacted?

Many resources are available to help determine this information in Georgia:

- Property appraisal, tax parcel information and the dam owner's name may be available online through sites such as the <u>Georgia Department of Revenue's</u> On-line Property Search or <u>qpublic</u>, a tax assessor site references many counties in Georgia. Access to information may vary significantly by county.
- Adjacent property owners/neighbors may provide sources of information for dam ownership.
- Local libraries, historical associations and museums are excellent sources of local information if searching for addresses, lat/long or a dam's name.
- The Georgia Soil and Water Conservation Commission manages a Watershed Dam Program that includes 357 dams. Dams can be identified by county-location online. See: <a href="https://gaswcc.georgia.gov/watershed-dams">https://gaswcc.georgia.gov/watershed-dams</a>

Dam owners may have responsibilities for maintaining their dam to ensure its structural integrity, the safety of those who recreate on or around the dam, and the liability associated with any potential dam failure. Maintaining dams over a long period of time may cost more when compared to the one-time cost of removal for obsolete dams that no longer serve a purpose.

#### Section 1.3 Physical Properties of the Dam

Once the dam owner has decided to move ahead with removal, information on the physical construction of the dam and surrounding structures should be collected for the permitting process. Researching the historical background of the dam may provide important information on the original design and materials used to build the dam. Understanding how the dam was built is critical for estimating costs of removal and designing the construction. The following information should be compiled:

- Any existing maps or photographs that show the dam and the surrounding landscape, such as historic aerials, USDA soil maps, topo maps, etc.
- Any existing technical plans on the dam, including 'as-builts' showing construction material.
- Dam dimensions (i.e., height and width.)
- Date constructed. If the date of a dam's construction is known but other construction details are lacking, local newspapers may be able to provide additional information about a dam's history. The Georgia Newspaper Project has digitized over 1 million pages of the state's newspapers; see: <a href="https://www.libs.uga.edu/gnp">https://www.libs.uga.edu/gnp</a>.
- Date modified (any significant additions, upgrades, repairs, operation and maintenance history).
- Construction material (e.g., earthen, rock, concrete, fill material inside dam, mixed, etc.).
- Original purpose (hydropower, amenity pond, water supply, etc.)
- Dam type is water impounded (creating a lake or pond behind the dam) or is the water freely flowing over the dam without causing significant modification of the shape of the river or stream upstream of the dam (known as a run-of-river dam)?
- Ancillary features.
  - For hydropower facilities:
    - Is there a powerhouse, turbines, sluice run, bypass channel, etc.?
    - Are the control structures currently functioning?
    - Do gates still open? Have they been removed?
    - Are panels missing?
    - Is there water passing through the dam?
  - For earthen dams:
    - Is there a roadway on the top of the dam?
    - Are there overflow spillways or discharge pipes, or leakage through the dam?
    - Are foliage/trees growing on the dam? If so, what is the size?

#### Section 1.4 Public Infrastructure

Removing a dam may impact infrastructure in the area surrounding the dam. A project manager or dam owner should identify public infrastructure upstream and downstream of the dam. At a minimum, upstream infrastructure should include the length of any impounded waters, which can be determined by measuring from the top of the dam back to the bed of the river.

- Note approximate distance from dam to bridges, abutments and retaining walls. For information on bridges by county, see <a href="https://bridgereports.com/ga/">https://bridgereports.com/ga/</a>.
- Identify roads either on the dam, or those in close proximity, identify road ownership (state, local, private) by contacting the county or the Georgia Department of Transportation.
- Identify water utility lines (e.g., sewer/stormwater) by contacting local public works departments.
- Identify underground and aerial utility lines such as gas, electric, telecommunications, and cable lines either by visual observation, contacting utilities such as local EMCs, Georgia Power and Atlanta Gas & Electric or searching https://www.georgia811.com/.
- Consult <u>Google Earth</u> to identify land uses, structures, infrastructure and other important features that might not be obvious or visible during a site visit.

# Section 1.5 Historical Significance of the Dam

Some dams and their associated structures are designated historic properties – defined as any prehistoric or historic district, site, building, structure, or object that is generally over 50 years old. Information on when a dam and associated structures were built and their historical significance will be needed for the permitting process. Books, photographs, maps, and other historical documents can provide details about historical dam ownership, construction, and use. Local libraries, college and university libraries, historical associations, and museums are excellent sources of information. To begin the process, access the following resources:

- Check to see if the dam is listed on the National Register of Historic Places by checking the National Register of Historic Places Database: <u>https://npgallery.nps.gov/nrhp.</u>
- Check to see if the dam has been identified by the Georgia State Historic Preservation Office within the Georgia Natural, Archaeological, and Historic Resources GIS: https://www.gnahrgis.org/.

If the dam is not designated as a historic structure, check to see if it is over 50 years old. If existing records do not note the age of the dam, some resources may help identify at least a date range within which it was constructed:

- Georgia's landscape has been captured by aerial photography since the 1930s. Black and white images, which can be searched at the county level, are available online through the Georgia Aerial Photograph collection: http://dbs.galib.uga.edu/gaph/html/.
- Historic Aerials: https://www.historicaerials.com/.
- Georgia's tax assessor records may also include historical information: https://qpublic.schneidercorp.com/.
- Sandborn Fire Insurance Maps: https://www.loc.gov/collections/sanborn-maps/about-thiscollection/.

The following resources may also help determine the age of the dam, provide additional information about its history or identify if it is located in a historically important area (for instance, battlefields, Indian mounds, hydroelectric plant, mill, commercial enterprise, etc):

- The Georgia Archives maintains a Historical and Cultural Organizations Directory: https://georgiaarchives.org/ghrac/directory
- The Georgia Historical Society maintains an Affiliate Chapter Program directory: https://georgiahistory.com/education-outreach/affiliate-chapter-program/affiliate-chapter-list-by-county/.
- Many Georgia communities and counties have a published local history, which may include basic information about the age of a dam and associated properties and identify relevant individuals and/or business interests.
- College libraries also have excellent resources: the University of Georgia, for example, has an extensive collection of local history resources, including historical images, maps and other documents. See: <a href="https://libs.uga.edu/hargrett/">https://libs.uga.edu/hargrett/</a>.
- The Digital Library of Georgia is a clearinghouse that provides access to statewide resources: https://dlg.usg.edu/.

- The Georgia River Network's guidebook series provides historical information and "little known facts" on many river features. <u>https://ugapress.org/series/georgia-river-network-guidebooks/"https://ugapress.org/series/georgia-river-network-guidebooks/</u>
- State Historic Preservation Office Public Files can provide information by topic (see "research appointments"): https://georgiashpo.org/staffdirectory-hpd
- Regionally or locally specific organizations can help with historical information, see: https://georgiashpo.org/clgs or https://georgiashpo.org/regionalplanning.

# Section 1.6 Current Regulatory Status of the Dam

Most obsolete dams are not regulated under any state or federal program; however, a subset of dams in Georgia is regulated for safety or for hydropower generation. Determining whether the dam is covered under any regulatory program is a critical step in the process.

#### **1.6.1 Georgia Safe Dams Program**

The Kelly Barnes Dam near Toccoa, Georgia, burst on November 6, 1977, after two days of heavy rain, causing 39 fatalities and leaving 60 injured (Sanders and Sauer, 1979). In response to that tragedy, then-President Jimmy Carter asked the Secretary of the Army to inspect 9,000 dams across the country, an undertaking that led to the creation of the NID and the establishment of the National Dam Safety Program. Forty-nine states now have state-run dam safety programs. GA EPD's SDP is authorized under the Georgia Safe Dams Act (OCGA §12-5-370 to 12-5-385) to "provide for the inventory, classification, inspection and permitting of certain dams in order to protect the health, safety and welfare of all of the citizens of the State by reducing the risk of failure of such dams to prevent death or injuries to persons."

Under this program, "Category I" dams include those for which failure would result in probable loss of human life. Category II dams include those where failure would not be expected to result in the probable loss of human life. Dams that do not meet either the Category I or Category II definitions are not covered under this program. To determine if a dam has been identified as Category I or II and is therefore covered under this program, visit the <u>State webpage</u> and click on the state's Inventory of Dams. The associated Excel spread sheet can be searched by dam name, county or lat/long. According to the State's April 2019 inventory, there are over 4,500 dams listed, including 690 Category I dams (a number subject to update over time). If the dam of interest is covered under the Georgia Safe Dams Programs, the dam owner must meet all of the responsibilities of the Act and the implementing Rules (Subject 391-3-8 Rules for Dam Safety). For dams covered under this program, locating all past dam inspections and dam safety reports will be helpful in the permitting process.

For Category I dams, it is important to note that Georgia's SDP specifies that "no person may remove a dam without the approval of the Director in accordance with the procedures required by the Act." For more information on the requirements of this program, see Section 3.4.3.

#### 1.6.2 Federal Energy Regulatory Commission Licensed Dams

The Federal Energy Regulatory Commission (FERC) regulates non-federal dams that produce hydroelectricity<sub>3</sub>. All FERC licensed projects have individual project numbers, and regularly submit

<sup>&</sup>lt;sup>3</sup> FERC does not regulate federal dams, including those operated in Georgia by the Army Corps of Engineers, for instance, Lake Lanier's Buford Dam.

compliance and other documents that address the physical details and characteristics of a dam. Information about FERC licensed dams is available via FERC's <u>hydropower page</u> which is the official repository for FERC license data. Information is also available from the Hydropower Reform Coalition's <u>portal</u>.

In Georgia, there are 18 operational FERC hydropower licenses; multiple projects can be covered under one license. The table below is a list of active FERC licenses in Georgia as of August 2019.

| ProjectNo. | Project Name                  | (KW)    | Licensee                          | Waterway            |
|------------|-------------------------------|---------|-----------------------------------|---------------------|
| 3102       | HIGH SHOALS                   | 1,027   | JASON & CAROL VICTORIA PRESLEY    | APALACHEE RIVER     |
| 2341       | LANGDALE                      | 1,040   | GEORGIA POWER CO (GA)             | CHATTAHOCHEE RIVER  |

Source: https://ferc.gov/industries/hydropower.asp. Note: Rocky Mountain Pumped Storage Project is primarily owned by Oglethorpe Power (75% owner) which will be the primary contact for licensing compliance and relicensing. Georgia Power is part (25%) owner of the project.

Decommissioned/Surrendered FERC Licenses: Some hydropower dams may no longer meet profitable power generation needs, no longer generate hydropower, or may need expensive maintenance to continue to operate. In these instances, hydroelectric dam owners may choose to surrender their license to FERC. Once the owner goes through the full process of license surrender and meets FERC's requirements for decommissioning (ensuring the site is not operational and meets safety requirements), the owner may choose to go through dam removal. Three of the dams listed above -- High Shoals, Langdale and Riverview -- are currently going through the decommissioning process.

FERC Exempt Licenses: Two types of operational hydropower projects are exempted from the full FERC licensing provisions: Conduit Exemptions and 10-MW Exemptions. Conduit exemptions are issued to hydropower projects on existing conduits (for example – a manmade canal), the primary purpose of which is not power generation. Conduit -exempted projects must be located on a conduit used for agricultural, municipal, or industrial consumption and are not integral to a dam. The 10-MW exemption is reserved for projects that generate 10-MW or less and will be built on an existing dam or project that utilizes a natural water feature. These exempted projects must still comply with any special conditions identified by the US Fish & Wildlife Service (US FWS) and the Georgia Department of Natural Resources (GA DNR), which exercise administration over the fish and wildlife resources, in the manner provided by the Fish and Wildlife Coordination Act (16 U.S.C. 661, et seq.) as required under Section 30(c) for the Federal Power

Act4 (FPA). General conditions for the 10-MW or less exemption are listed below and may be granted for an existing dam or at a natural water feature, such as a waterfall. Conditions include:

- No expiration
- 10 MW or less
- Located at an existing dam or a natural water feature
- Subject to mandatory fish and wildlife conditions, section 30(c) of FPA
- Requires NEPA and NHPA analysis
- Project boundary must enclose dam and reservoir
- Applicant must possess all real property rights at time of filing unless on federal land

The table below identifies the three FERC Exempt hydropower dams in Georgia as of August 2019. Each of these projects are described as Non-Conduit Exemptions or 10-MW Exemptions. https://ferc.gov/industries/hydropower.asp

| ProjectNo. | Project Name          | (KW)  | Exemptee                         | Waterway      |
|------------|-----------------------|-------|----------------------------------|---------------|
| 7238       | DALESMOORE PLANTATION | 100   | FORBES H. MATHEWS                | RED OAK CREEK |
| 7141       | MILSTEAD DAM          | 1,000 | MILL SHOALS HYDRO COMPANY, LLC   | YELLOW RIVER  |
| 2568       | PORTERDALE            | 2,520 | VC PORTERDALE HYDROELECTRIC, LLC | YELLOW RIVER  |

Revoked FERC Licenses On rare occasions, a permittee can have its license revoked by FERC, which has the enforcement authority to take this action under the FPA. FERC may require additional provisions in revoking the license, such as decommissioning all hydropower equipment. Dam owners are not automatically required to remove dams once a license is revoked. In October 2014, the FERC license was revoked for Juliette Dam located near Forsyth, Georgia. The revocation order required all hydropower generating equipment to be decommissioned.

<sup>4 &</sup>lt;u>16 U.S.C.</u> § <u>823a(c)</u> 30(c) of FPA - The construction, operation, and maintenance of the exempt project must comply with any terms and conditions that the US FWS, NMFS, and GADNR have determined are appropriate to prevent loss of and/or damage to fish or wildlife resources or otherwise to carry out the purposes of the Fish and Wildlife Coordination Act, as specified in exhibit E of the application for exemption from licensing or in the comments submitted in response to the notice of exemption application.

# **STEP 2: RESEARCH THE RIVER AND SURROUNDING LANDSCAPE**

Researching the river ecosystem and surrounding riparian area around the dam is critical to understanding the potential impact of dam removal. This section provides resources for the project manager or dam owner preparing to research the area surrounding the dam.

#### Section 2.1 Basic Description of the Resource

In addition to hard copies of maps of a river and its surrounding landscape, the United States Geological Survey (USGS) National Map Viewer (https://viewer.nationalmap.gov/advanced-viewer/) is a good resource for basic information that may be needed for the permitting process:

- Zoom in on the topo map to see the official name from the US Geographic Names Information System (GNIS) for a stream or river. Small streams may not have an official name.
- Identify tributaries and see if there are confluences with other major rivers up or downstream.
- Identify the stream by segment description, if necessary; e.g. "from Hwy 110 to the confluence with Big Creek."
- If a waterbody is impounded, determine if the impoundment has its own name that differs from that of the dam. Many dams can be found in the "Dams" layer, a sublayer within the "Cultural Points" group layer in the "GNIS" layer.
- Turn on the "Watershed Boundary Dataset" layer to obtain a watershed Hydrologic Unit Code (HUC) name and number.
- USGS stream gage locations are visible in the "Point Event" sublayer within the "National Hydrography Dataset" layer.
- Obtain land cover classifications and topographic/elevation data from various layers.

Other good resources for information about rivers and streams include:

- SARP's <u>Southeast Aquatic Barrier Prioritization Tool</u> provides information about various aquatic passage barriers, including dams.
- The <u>USGS Stream Stats site</u> provides estimated stream flow statistics and various watershed characteristics, including land use.

American River's *Removing Small Dams: A Basic Guide for Project Managers* (pg. 16) provides an excellent description of a process to complete geomorphological surveys and base mapping, which will be needed to assess hydraulics and sediment. Overall this guide states that the survey should include:

- 1. Cross sections of the river and adjacent land, upstream and downstream of the dam.
- 2. A longitudinal profile of the "thalweg" (i.e., the deepest part of the river channel) through the impoundment, upstream and downstream of the dam.
- 3. A survey of the depth of soft sediment throughout the impoundment (often described as the "depth of refusal," or the point where a rod hits a harder surface and cannot easily be pushed further down).

- 4. A delineation of the resource areas that will be affected, including wetlands, and ordinary high water mark and low water marks.<sup>5</sup> (For additional information on wetlands and sediment, see Sections 2.4 and 2.5, respectively.)
- 5. A hydrology and hydraulics (H&H) assessment to assess the magnitude and frequency of flows in the river (including depths, velocity, and scour potential).

# Section 2.2 Water Quality

Information about whether the dam has had documented impacts on water quality may be needed for the permitting process. This information can also be used if applying for grants or funding tied to demonstrating that water quality may be improved by dam removal. According to EPA, "[v]irtually every dam will have an impact on the river or stream where it is located, although the types and extent of the impact will vary based on the size, operation, and purpose of the dam as well as the size and general characteristics of the waterway. In general, increased retention time of water behind dams causes physical, thermal, and chemical changes to take place both in the impounded and downstream waters," (EPA 2016). These changes may impact water quality relating to nutrients, temperature, sediments, algal blooms, dissolved oxygen, pH, hydrogen sulfide, iron, manganese, and other metals. The presence of the dam may also cause impacts to aquatic life as measured through biological sampling and metrics, including macroinvertebrates (e.g. crayfish or dragonfly larvae), mussels, or fish. For more information on water quality and dams under the CWA, as well as the potential for grants to address dams that cause water quality impacts, see EPA's Frequently Asked Questions on Removal of Obsolete Dams.

GA EPD and volunteers through programs such as GA EPD's Adopt-A-Stream program collect water quality data and information on many rivers, streams and lakes. The following resources provide access to readily available water quality data:

- GA EPD assigns all waterbodies a "designated use," establishing the waterbody's water quality goal. In Georgia, there are six designated uses (a) Drinking Water Supplies, (b) Recreation, (c) Fishing, (d) Wild River, (e) Scenic River and (f) Coastal Fishing each having associated narrative and numeric standards. Waterbodies may have more than one designated use. To determine a waterbody's designated use(s), search for it by name in the State Water Quality Standards document.
- If Drinking Water Supply is one of the designated uses, note that raw water intake structures in the river could be impacted by dam removal. For example, an upstream intake could be exposed when the dam is removed and the impounded water is lowered, or a downstream intake could be impacted by sediments released during removal.
- GA EPD monitors waterbodies across the state to assess water quality as required under Section 305(b) of the CWA. Using the State's Assessment Methodology, GA EPD compares the results with the State Water Quality Standards to determine if waterbodies are meeting their designated use. That information, submitted to EPA in the State's Integrated 305(b)/303(d) Reports, may

<sup>&</sup>lt;sup>5</sup> Ordinary High Water Mark is defined as, "...that line on the shore established by the fluctuations of water and indicated by physical characteristics such as clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas." Corps Regulatory Guidance Letter, 2005 (RGL 05-05), and 33 CFR 328.3(e)

include information relating to water chemistry or biological indicators (such as macroinvertebrate or fish), or information on historical or legacy pollutants (such as PCBs or mercury). The Georgia Environmental Management and Assessment System (GOMAS) database contains GA EPD water quality data. The public portal can be found at https://gomaspublic.gaepd.org/

- Waters that have been identified as impaired can be viewed in the ArcGis Hub for Georgia.
- Georgia provides access to <u>GIS Data Sets</u> for their Integrated 305(b)/303(d) Reports that, according to GA EPD, also allow access to coverages for river basins, groundwater recharge areas, HUCs, landfills, RiverCare 2000, and the Georgia GIS Clearinghouse.
- Georgia's Adopt-A-Stream program has a robust data set that may have relevant water chemistry and biological data.
- Local stakeholders, neighbors and newspapers, among other sources, may have anecdotal accounts of water quality issues.

#### Section 2.3 Wildlife Resources

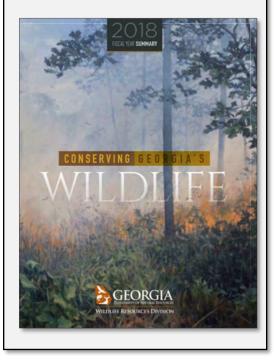

Georgia is part of a globally recognized biodiversity hotspot for aquatic life. With 265 species of freshwater fishes, it ranks third in the U. S., surpassed only by Alabama and Tennessee. (To learn more, see sidebar or go to <u>Georgia Freshwater Fish</u>).

The <u>Wildlife Resources Division</u> (WRD) of the GA DNR regulates hunting and fishing, provides protection for endangered wildlife, and conserves Georgia's wild resources. It has many online resources for exploring the presence of species and critical habitats. Identifying key species and habitats, both aquatic and terrestrial, in the area affected by the dam removal is a requirement of the CWA Section 404 permitting process. The following questions should be addressed:

• Are there species of conservation concern present in the project area? Use the <u>GA DNR Data Portal</u> to query at the HUC 10 level. Submit a request for an Environmental Review from the Wildlife Resources Division to identify species of concern at the site.

# **Georgia's Aquatic Biodiversity**

According to GA DNR's 2018 Annual Wildlife Report, Conserving Georgia's *Wildlife*, "Georgia is one of the richest states in freshwater aquatic biodiversity, ranking among the top five in the number of native species of crayfishes (70), fishes (265), mussels (127) and aquatic snails (84). However, Georgia also ranks among the top states in imperiled freshwater aquatic species. A recent assessment recognized 152 imperiled aquatic species in Georgia, more than half of which have a significant part of their global range within the state's boundaries. Approximately 22 percent of Georgia's freshwater fishes, 28 percent of mollusks and 36 percent of crayfishes are classified as imperiled or critically imperiled in the state. Yet even these numbers understate the problem because they do not include the 48 species, mostly mollusks, considered extirpated from Georgia waters."

- Are species or habitat in the project area identified as a priority in the State Wildlife Action Plan?
- Are there economically or recreationally important aquatic or riparian species in the project area?
- Consider how removal of the dam may positively or negatively impact species. For instance, will dam removal allow fish movement above and below the dam? Will released sediment affect species or their habitats downstream?
- Will migratory fish species (e.g., American Eel, Shad, white basses, Robust Redhorse, or sturgeons) stand to benefit?
- Will non-migratory species (e.g., endemic species like the Chattahoochee Bass and Shoal Bass) benefit?
- Would dam removal create, restore, or enhance habitat for species (e.g., support mussels; increase aquatic diversity; enable spawning by species of concern)
- Are invasive species present i.e., fish such as Snakeheads, Blueback Herring, Spotted Bass or Asian Carp, shellfish such as zebra mussels, or plants such as *Hydrilla*? Are they present above and below the dam? Would dam removal allow invasive species to expand their distribution? Review the complete list of invasive species and the efforts to address them in Georgia at the WRD's Invasive Species Strategy.

The US FWS and the National Marine Fisheries Service (NMFS or NOAA Fisheries) are charged with protecting threatened or endangered (T&E) species and designated critical habitat covered under the Endangered Species Act (ESA). To determine if T&E species are present, explore the US FWS's Information for Planning and Consultation (IPAC) tool for species under the jurisdiction of the US FWS. Contact NOAA Fisheries for information about species under their jurisdiction. If T&E species are present, be sure to note the requirements to consult with the US FWS by following the steps in the IPAC tool or directly with NOAA Fisheries, more fully discussed in Step 3. Note that impounding water through dams has caused or contributed to the endangerment of some imperiled species, particularly those adapted to free-flowing water throughout the southeastern US. Removing dams may provide opportunities for the restoration of local populations of some species.

#### Section 2.4 Connectivity

Dams act as barriers to aquatic organism passage, significantly altering the migration of native anadromous, catadromous, and potamodromous fish.6 Removing dams may provide significant benefit for increasing the range of these fishes.

SARP's <u>Comprehensive Southeast Aquatic Barrier Inventory</u> includes over 137,000 dams and approximately 25,000 assessed road stream crossings. Together with the Conservation Biology Institute, SARP has created an online tool to prioritize these barriers for removal or bypass based on ecological metrics. This tool, called the <u>Southeast Aquatic Barrier Prioritization Tool</u>, allows users to visualize the inventory of barriers, understand information about each barrier's river network, and identify top priority structures for removal based on the geographic area of interest. The results can then be used to work with GA ACT members and landowners to implement passage projects. The tool can be used in the planning process to understand the impact of dam removal, including, for example, the number of reconnected river

<sup>&</sup>lt;sup>6</sup> Anadromous species live part of their life cycle in salt water but return to freshwater to spawn. In Georgia, these species include American Shad, Hickory Shad, Blueback Herring, Atlantic Sturgeon, mullet and Striped Bass. Catadromous species, such as American Eels, live in freshwater and return to salt water to spawn. Potamodromous species live entirely within freshwater; however, they spend much of their lifecycle downstream and migrate upstream to spawn. In Georgia, Robust Redhorse is an example of a potamodromous species.

miles. To explore how many river miles may be gained, click on "Start Prioritizing", then "Prioritize dams." Once the map opens, select "State" then begin typing, "Georgia." Zoom to the area of interest and click, "Select dams in this area." Once a dam is selected, the tool will provide information on Feasibility & Conservation Benefit, Miles Gained, Dam Height, Threatened & Endangered Species, and more.

#### Section 2.5 Wetlands

The presence of jurisdictional wetlands regulated under Federal law is an important consideration in the regulatory permitting process. Wetlands are defined by EPA and the Corps as "...areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas." (See EPA Section 404 of the Clean Water Act).

Wetlands may have been present prior to the dam, or the construction of the dam may have created wetlands adjacent to the impounded area of the river or stream over time. Dam removal could have direct and immediate effects on any existing wetlands within the project area directly around the dam. Natural wetlands may have existed on the lowest terraces of the floodplain before impoundment, and removal of the dam could prompt reestablishment of the original wetland community. Alternatively, wetlands created by a dam could be cut off from their water source post-removal, if the river drops back down into its original channel. These wetlands would then have relict hydric soils, (soils that are either permanently or seasonally saturated by water), and the community could eventually revert to an upland.

Topography is key to considering if wetlands are present. Incised channels in narrow valleys may not typically have wetlands adjacent to them. Conversely, if the valley is relatively wide and flat, and the floodplain is not cut off from the river, impoundments could alter the hydrology of the middle terraces enough to saturate the soil and create new wetlands. Another scenario is that a moderately incised channel, once impounded, could overflow onto a relict floodplain, re-hydrating soils and reestablishing wetlands. Other circumstances may result in creation of wetlands.

A qualified wetland delineator should be engaged to identify and map all wetlands that would or could be affected by the project. A list of consultants may be available from the Corps. Regulatory agencies may choose to make a distinction between natural and man-made wetlands for purposes of permitting and mitigation. They may also consider the relative environmental condition and functionality of the wetlands, which means that a functional assessment may also be required. There are various functional assessment methods available, one or more of which may be applicable when used by a qualified wetland assessor.

# 2.6 Sediment

Addressing sediment will likely be a key component of working with the regulatory agencies during the permitting process. All rivers contain sediment, which consists of sand, silt, clay, gravel, rocks, minerals, and organic matter. The movement of sediment through waterbodies is an important geophysical process that distributes nutrients and other materials across the landscape. Dams slow the flow of water and impede the natural movement of sediment downstream. Sediment may build up behind a dam over time and is an important issue to consider in dam removal projects. Waters downstream of a dam may have been sediment-starved while the dam was present, and dam removal will play an important role in restoring natural sediment transport dynamics. However, release of sediment can cause abrasion or bury aquatic plants, animals, or habitat (EPA 2016). Sediment can also be contaminated with pollutants,

putting downstream drinking water and aquatic life at risk if released without remediation. Properly collecting and analyzing data on the quantity and quality of sediment upstream of a dam is critical to safely managing sediment in a removal project. The process is iterative, starting with readily available information that is reanalyzed as more data becomes available (Subcommittee on Sedimentation, 2017).

Sediment quantity can vary depending on the dam design, location, and historic land use surrounding and upstream of the body of water. For example, some low-head dams may have comparatively little sediment trapped within their impoundments due to the constant flow of water over the dam. Measuring the relative sediment volume is done by finding the ratio of the existing reservoir sediment mass to the average annual sediment mass entering the reservoir (Subcommittee on Sedimentation, 2017). If the volume is determined to be negligible, the Corps may determine that no extensive sediment investigations are needed. Volumes that are greater than negligible will likely require further investigation. Work with the Corps to determine how the sediment will be addressed during removal.

A due diligence review will be needed to determine if there is reason to believe the sediment behind the dam may be contaminated by pollutants. Contamination occurs when pollutants enter an upstream waterbody through stormwater runoff, effluent discharge, or illegal dumping; the slow water behind the dam causes contaminants to settle and accumulate in the sediments (Subcommittee on Sedimentation, 2017). The potential for contamination can often be informed by investigating the historical land use and human activities of the upstream watershed. For example, sediment contamination could be the result of industrial manufacturing upstream of the dam. Extensive land clearing activities for agriculture or development and high proportions of impervious surface are other indicators of potential sediment contamination. Work with the Corps to determine if sediment chemistry sampling and analysis is needed. For references that may be helpful, see the EPA's Methods for Collection, Storage and Manipulation of Sediments for Chemical and Toxicological Analyses: Technical Manual or the Dam Removal Analysis Guidelines for Sediment.

# Section 2.7 Federal Emergency Management Agency (FEMA) Flood Hazard

FEMA creates flood hazard maps that outline the flood risk areas in municipalities around the country. Dam removal projects located in Special Flood Hazard Areas may have special requirements. For more information, review FEMA's Flood Zone Maps and their handbook Living with Dams: Know Your Risks or https://www.fema.gov/media-library/assets/documents/28161

#### Section 2.8 Historical Use of the River

If possible, compile information on the cultural importance of the river prior to the dam's creation. Names associated with the pre-dam natural features of the river may indicate its original use, such as references to shoals, ferry crossings, wildlife or aquatic life. These references may also indicate how Native Americans and early settlers used the river as communal fishing grounds or as a location for fishing weirs, for example, before the dam was built. Restoration of the river after dam removal may also restore some of these historical uses or cultural attributes that we buried under impounded waters.

#### Section 2.9 Recreation/Public Safety

Information on the river's recreational uses may or may not be needed for the permitting process but could be of value as the dam owner or project manager conducts community outreach on the project. Understanding the current recreational uses of the affected waterbodies is an important step in

understanding who might be affected by the project. A dam removal project usually changes the aesthetics and function of the waterbody into a more natural state. If the dam impounds water, removal of the dam can result in the loss of activities that require lake conditions, such as sport fishing for lake-dependent species, experiencing lake-like conditions in a watercraft, and swimming. Conversely, removal of the dam may improve paddle sports and provide sport fishing opportunities for species adapted to free-flowing water. Dam removal can also provide opportunities to develop water trails, which can be economically important to rural communities (See Section 2.11).

Dams can be a physical barrier to recreation as well as a safety concern due to dangerous hydraulic conditions below the dam (Wright & Tschantz, 2011). Many of the most dangerous dams for recreational users are low-head or run-of-the-river dams. They are characterized by their low height, allowing water to consistently flow over the top of the dam. The water falling over the dam creates circulating currents that trap people and objects underwater. The hydraulics are practically inescapable for anyone or anything passing over the dam or even those who approach the dam from below and become entrained in the 'boil'. There is no national database to track the deaths associated with dams, however researchers at Brigham Young University compiled a database listing at least 555 deaths at 276 low-head dams since the 1950s.

Unmaintained dams can also be subject to infrastructure failures. Extreme weather events that increase the volume and force of water pushing against a dam can cause devastating breaches. The potential for dam failures may increase as extreme weather events increase. The South Carolina Department of Health and Environmental Control reported that 32 dams failed in South Carolina during an extreme storm event in October 2015, including 17 in Richland County alone. These failures, "exacerbated already dangerous flooding conditions and caused mandatory evacuations of communities. The threat of weakened, rain-soaked dams failing continued well after the storm had passed, causing great concern from the threat of continued evacuations in communities already dealing with property damage and safety concerns." (EPA 2016). The Association of State Dam Safety Officials is the national organization dedicated to improving dam conditions and safety in the US. For more information, see the ASDSO webpage.

# Section 2.10 Ecosystem Services and Resiliency

A free-flowing river moves in four dimensions: laterally across the floodplain, longitudinally from the headwaters to the ocean, vertically from the surface to the groundwater, and temporally with its flow varying across the timeline. Dams impede a river's ability to move in these four dimensions. Healthy, connected, free flowing rivers provide a wide variety of ecosystem services (Dandekar, 2018):

- Secured food sources in the form of healthy fisheries, aquaculture and agriculture;
- Reduced floodwater intensity by allowing the river to spread into the floodplain, reducing the force and height of the water in the channel;
- Protected biodiversity within the river;
- Improved water quality from higher dissolved oxygen levels, lower temperatures and nutrients;
- Protected human health by minimizing stagnant waters associated with disease spreading vectors;
- Protected coastlines against erosion and saltwater intrusion by transporting sediment downstream where it builds and sustains coastal marshes;
- Increased opportunities to experience the religious, spiritual, and cultural importance of free-flowing rivers, such as baptisms, tribal ceremonies and swimming.

#### Section 2.11 Economics

Dam removal can create new economic opportunities for communities through the development of ecotourism. Paddling is a growing sport with a meaningful impact on Georgia's economy. There are approximately one million paddlers in the state (Georgia River Network, n.d.) that contributed \$11.3 billion in economic benefits in 2016 (Georgia State Parks, 2016). Access to free-flowing rivers brings customers to outfitters, lodges, restaurants, grocery stores, retail stores, and transportation companies. River-focused tourism can also stimulate the economy in indirect ways through an increase in tax revenue, real estate value, and employment opportunities (Warren, 2015). Investing in infrastructure for outdoor recreation attracts new businesses and an active workforce, strengthening the local economy and the social wellbeing of the community (The Outdoor Industry Association, 2017). According to the Outdoor Industry Association, the removal of the City Mills and Eagle & Phenix dams in Columbus, Georgia brings recreational visitors valued at over \$42 million per year to the surrounding area (See Case Study No. 1 for more information).

Water trails, the sections of rivers, wetlands, and coastal areas with public access for recreational boating, kayaking, canoeing, paddle boarding, and fishing are the aquatic equivalent of hiking trails. Currently there are 18 recognized water trails in Georgia that combine to cover 1,210 miles of river, 170 miles of coastal saltwater, and 400,000 acres of wetlands. Sixteen more are in development. These areas provide opportunities for social and economic development. For example, the 58 miles of the Chattooga River designated as a National Wild and Scenic River draws 43,000 visitors a year, generating roughly \$2.7 million in a six-county area (Georgia River Network, 2018). The proposed 52-mile Chattahoochee Valley Blueway is estimated to increase the total economic output in the surrounding 8-county region by over \$3.2 million annually (Blair, 2012). For more information, visit Georgia River Network's Water Trails webpage.

Trout fishing can offer representative figures for the popularity and economic importance of fishing in free-flowing rivers and streams. The value of trout fishing in Georgia is estimated to exceed \$172 million annually, with more than 100,000 trout fishing licenses sold each year (Georgia Department of Natural Resources, n.d.). Many migratory fish are important for commercial and recreational angling. Without a barrier, they can migrate further, expanding fishing opportunities to anglers upstream. American and Hickory shad are athletic seafaring fish that annually migrate to freshwater rivers and streams between February and May. These acrobats put up quite a fight, offering thrilling experiences to anglers by taking to the air in an effort to shake the hook, leading to new interest in shad fishing in Georgia.

# STEP 3: UNDERSTANDING THE REGULATORY PROCESS FOR OBTAINING A PERMIT FOR REMOVAL OF DAMS IN GEORGIA

#### Section 3.1 Federal Regulatory Authorities Overview

Section 404 of the Clean Water Act requires that a permit be obtained before dredged or fill material can be discharged into jurisdictional waters of the United States, with some limited exemptions for forestry, ranching, and farming activities. The Corps is the primary agency for issuing Section 404 permits, conducting or verifying jurisdictional determinations, as well as enforcing permit conditions (for more information see EPA 404 Permit Program). The EPA works closely with the Corps to interpret policy, guidance, and environmental criteria used in permitting, including by ensuring that water quality is protected as outlined in the Section 404(b)(1) guidelines (40 CFR Part 230).

Section 10 of the Rivers and Harbors Act (1899) governs the construction and modification of structures created in navigable waters of the United States. A list of these waters is maintained by the Corps. On a case-by-case basis, dam breaching, dam modification or dam removal activities may require a permit under Section 404 or Section 10. The Corps has guidance stating that "...if a dam operator modifies or deviates from normal operation of the dam in such a manner that bottom sediment accumulated behind a dam could be removed and transported downstream through the dam, either deliberately or accidentally, that activity may require a permit pursuant to Section 404." (Regulatory Guidance Letter (RGL) 05-04).

Additionally, 33 USC 408 (Section 408) requires the Corps to process requests by private, public, tribal, or other federal entities to make alterations to, or temporarily or permanently occupy or use, any federally authorized Civil Works project. In addition to structures, alteration of flowage easements and other associated areas are subject to Section 408 review. All Corps Districts are currently developing Standard Operating Procedures (SOP) for requests to alter Corps Civil Works projects. The Corps Project Manager (PM) will determine whether or not a proposed project has potential to adversely affect a federally-authorized project.

#### Section 3.2 Corps Permitting Overview

The South Atlantic Division of the Corps includes five districts in the Southeastern U.S.: Charleston, Jacksonville, Mobile, Savannah, and Wilmington. Applications for federal permits to remove a dam located within the geographic boundaries of the State of Georgia would be processed by the Regulatory Division of the Savannah District. If a dam removal project is proposed on waters forming State boundaries, applicable Corps Districts with adjoining regulatory boundaries will determine the "lead" District for permit application and processing. Persons or parties planning dam removal projects on rivers or streams forming Georgia state boundaries should begin that process by contacting the Savannah District office for a determination.

As detailed on the Savannah District's <u>E-Submittal of Applications</u> page, permit application submittals are split into the Piedmont or Coastal geographic regions of the Savannah District. The address and email for the two Corps Branch offices are:

Piedmont Branch Office 4751 Best Road, Suite 140 College Park, Georgia 30337 <u>Cesas-op-fp@usace.army.mil</u> Coastal Branch Office 100 West Oglethorpe Avenue Savannah, Georgia 31401 <u>Cesas-op-fc@usace.army.mil</u>

# Section 3.3 Individual v. General Permits

Two types of Section 404 permits may be used to authorize a dam removal project – an Individual Section 404 Permit or one or more general permits. There are also two types of general permits – Regional General Permits and Nationwide Permits (NWP). The Corps District office decides on a case-by-case basis which type of permit is needed. Large, complex projects with potential for significant impacts may require review and authorization under the individual permit process. Small projects expected to have minimal adverse effects may be handled under the general permit process.

Applicants should begin to collect the information on their project as outlined in Steps 1 & 2 for initial scoping of the project. Once that is done, but prior to completing and submitting any permitting forms, applicants should begin the informal process by discussing the proposed project with the appropriate Corps office. After that initial discussion, the Corps will schedule a meeting with participating state and federal agencies of the Interagency Review Team7 (IRT) and then coordinate the review process with IRT members. For example, they will ensure that the presence of threatened and endangered species under the Endangered Species Act is reviewed by US FWS or the National Marine Fisheries Service NOAA Fisheries, and they will coordinate on any additional permits needed by the applicant.

During the IRT meeting, the applicant may receive information regarding permitting options and application requirements, as well as requests for additional information. The Corps may also assign a Project Number and a Corps PM. Maintaining clear and open lines of communication with the Corps PM is the best way to facilitate timely and accurate Section 404 regulatory review of the proposed project.

The length of the Section 404 regulatory process will depend in large part upon the type of permit required, the complexity of the proposed project, quality and thoroughness of information submitted by the applicant, and the applicant's responsiveness to requests for information from the Corps.

Once instructed by the Corps PM to do so, the applicant can begin the process of applying for a permit by following the

# Nationwide Permits

NWPs that have been, or potentially could be, used for dam removal in Georgia:

#### NWP No. 3 Maintenance

- The repair, rehabilitation, or replacement of any previously authorized fill.
- The removal of previously authorized structures.

<u>NWP No. 27 Aquatic Habitat</u> <u>Restoration, Enhancement, and</u> <u>Establishment Activities</u>

- Activity must result in net increase in aquatic resource functions.
- Activity must result in aquatic habitat that resembles reference conditions.

<u>NWP No. 33 Temporary</u> <u>Construction, Access, and</u> <u>Dewatering</u>

• Temporary structures, work, and discharges necessary for construction activities.

<sup>&</sup>lt;sup>7</sup>The IRT is comprised of the U.S. Environmental Protection Agency, U.S. Fish and Wildlife Service, Georgia Environmental Protection Division, Georgia Coastal Resources Division (coastal resources), and the U.S. National Oceanic & Atmospheric Administration, National Marine Fisheries Service (coastal resources).

instructions set out on the webpage, <u>Submitting E-Applications to the Savannah District, Regulatory</u> Branch. The Savannah District provides more detailed information on the NWP permitting process on its <u>Regulatory Permitting webpage</u>.

**Individual Permit:** If the Corps determines that the project will require an individual permit, the applicant must complete Form 4345 (also called CESAS Form 19, which is a joint application with the State of Georgia) and submit it to the Corps.

**Nationwide Permits**: If the Corps determines that the project can proceed under one or more NWPs, they will determine which NWP(s) is/are most appropriate. It should be noted that on January 6, 2017, the Corps published a national notification of a new NWP, *NWP No. 53 Removal of Low Head Dams* for "structures and work in navigable waters of the United States and discharges of dredged or fill material into water of the United States associated with the removal of low-head dams." Each District makes its own determination of the use of NWPs within its area of geographic responsibility. The Savannah District elected not to authorize use of *NWP No. 53*. Therefore, other NWPs may be applicable for the removal of low-head dams. For instance, NWP *No. 3 for Maintenance, NWP No. 27 for Aquatic Habitat Restoration, Enhancement, and Establishment Activities*, or *NWP 33 for Temporary Construction, Access, and Dewatering* (see sidebar pg 25).

Relevant forms and information for the permit application:

<u>Pre-Construction Notification (PCN)</u>: This is the basic form to fill out for use with certain NWPs. Note that these forms are updated when the Corps renews the NWPs, typically on a 5-year schedule. The current form is dated 2017.

**Regional Conditions:** On page 2 of the PCN, there is a reference to the "RC A and Appendix A." This refers to the *Savannah District's 2017 Nationwide Permit Regional Conditions*, which can be found at the bottom of the District's Regulatory Permitting Page or through this link. The Regional Conditions document provides applicants with detailed information on how to apply for a NWP as well as valuable resources and related links.

#### Section 3.4 State Regulatory Overview

The State of Georgia has permitting procedures in multiple program areas that applicants must follow when considering dam removal.

#### Section 3.4.1 Section 401 Water Quality Certification

The Corps' Regional Conditions specify that the GA EPD has issued a conditional Section 401 water quality certification for nationwide permits. Each project does not need an individual Section 401 certification from the State but must meet the general conditions for the NWP certification. One of those conditions requires that GA DNR be notified before beginning work on any and all NWP authorized projects. Appendix A notes that a copy of the PCN with project plans must also be submitted to the GA EPD and, where applicable, to the GA DNR Coastal Resources Division (GA CRD). Instructions for coordinating with and submitting that information to GA EPD along with forms that must be filled out and submitted to GA CRD are included in Appendix A.

#### Section 3.4.2 State of Georgia Buffer Requirements

If the dam removal could potentially involve work within Georgia's State mandated stream buffers (O.C.G.A. Section 12-7-6(b)(15-17) of "The Erosion and Sedimentation Act of 1975"), Appendix A of the NWP Regional Conditions outlines the requirements to determine if a buffer variance is needed from the GA EPD. Applicants are encouraged to visit Georgia EPD's webpage, view the instructions for erosion and sedimentation forms, or contact GA EPD at (404) 651-8554, for further guidance on buffer determinations and variances. For a direct link to the State's Rules see GA R&R - GAC - Rule 391-3-7-.05. Buffer Variance Procedures and Criteria and GA R&R – GAC – Rule 391-3-7-.11 for Coastal Marshlands Buffer Variance Procedures and Criteria.

### Section 3.4.3 NPDES Permitting for Construction Stormwater Permits

If one or more acres of land is disturbed during the dam removal project, an NPDES Stormwater Construction Permit will be needed. Specifically, a permit is needed, "where construction activities will result in contiguous land disturbances equal to or greater than one (1) acre or tracts of less than one (1) acre that are part of a larger common plan of development with a combined disturbance one (1) acre or greater." (EPD Construction Stormwater Permit Fact Sheet, 2018). Step-by-step instructions for applying for coverage under a general permit can be found on GA EPD's Construction Stormwater General Permits Webpage.

### Section 3.4.4 Georgia Safe Dams Program

As outlined under Step 1, to be considered a dam under the <u>Georgia Safe Dams Program</u>, a structure must either be at least 25 feet tall (vertical height) or store at least 100 acre-feet (volume) at maximum capacity. If a structure meets *either* of these criteria it would be considered a dam under the Georgia Safe Dams Act (Act) and then further classified as Category I or Category II. It is important to note that these classifications are not based on the condition of the dam but rather on the potential consequences should it fail. Category I structures are those that if they failed would probably result in loss of life. Category II dams are those without any structures, such as homes or businesses, located in a potential flood zone.

Georgia is home to approximately 500 Category I dams and approximately 4,000 Category II dams. Additionally, The Nature Conservancy and SARP estimate that there are more than 30,000 total dams in Georgia, most of which fall below the height and storage criteria to be defined as a dam under the Act. These structures, along with any dam owned or regulated by the FERC, are considered exempt from the Act. Other dams considered exempt are those that have less than 15 acre-feet of storage, regardless of height, or those that are less than 6 feet tall, regardless of storage.

When a dam is classified as Category I, the owner is given 180 days to submit the permit package to bring the dam into compliance with the Act. In general, these owners have several options for addressing the dam's compliance, including upgrading the dam to Category I standards, changing the classification of the dam by either modifying the dam or removing the hazards downstream, or breaching the dam. There are pros and cons to each of these options that an owner must consider before determining the best option. Generally, upgrading the dam to Category I standards will be the most expensive option, initially. Breaching the dam is often the cheaper option when considering only engineering and construction costs. Other factors, such as environmental impact and loss of property values, can make breaching a less viable option.

According to the <u>Georgia Safe Dam Program's Frequently Asked Questions</u>, owners who choose to breach a dam are required to fill out a breach application and retain an Engineer of Record to submit design plans for safely carrying out the effort. Once the plans are approved and the dam has been breached, owners will have no further responsibilities under the Safe Dams Program. The Safe Dams Program maintains a list of qualifying Engineers of Record on their <u>webpage</u>.

The Georgia Safe Dams Program notes the importance of recognizing that in some cases, removing a dam may increase the potential risks to downstream areas. Such would be the case for a dam that provides flood protection. Careful consideration should be given to the impacts of removing a dam that protects downstream populations from frequent flood events. Such a dam may be suited to partial removal, leaving a lower structure to protect against frequent flooding. (United States Society of Dams Guidelines for Dam Decommissioning Projects, July 2015).

#### Section 3.4.5 State Historic Preservation Office (SHPO) Coordination

Under Step 1, the applicant should have collected relevant historical background information on the dam. That information will be used when the Corps Project Manager is assigned to coordinate review of the project with the State Historic Preservation Office (SHPO). Section 106 of the National Historic Preservation Act (NHPA) requires that federal agencies take into account the impacts of their "undertakings" on historic properties. "Undertakings" are anything a federal agency does, funds, or regulates in some way (such as, permits, licenses, etc.). More information can be found on the Advisory Council on Historic Preservation's webpage.

The overall purpose of Section 106 is to take into account historic properties during a project's planning process. As such, SHPO, the federal agency, and other consulting parties (tribes, the public, etc.) should be involved early and often throughout the project's timeline. Those parties can provide feedback on alternatives, technical assistance, and similar comments. That being said, the Section 106 process often cannot be completed until a preferred alternative has been selected as final, the scope of work is known, and project plans are near completion. Without this information, impacts to historic properties cannot be completely assessed. Additionally, considering the proximity to water and the nature of dam removal causing ground disturbance, keep in mind that an archaeological survey may need to be completed by a Secretary of the Interior's Qualified Professional. All surveys needed are the responsibility of the applicant.

Although some federal agencies delegate the responsibility for this review to applicants, the Corps is one of the federal agencies that <u>does not</u> delegate their Section 106 responsibilities. Applicants should be in constant contact with their Corps Project Manager, who understands the process and will consult with an internal Corps cultural resource specialist and, if necessary, the SHPO office. Formal consultation with SHPO may or may not be needed and will be determined by the Corps Project Manager. Be responsive to the Corps Project Manager's requests for any additional information to keep the process moving forward. Applicants should note that one outcome of a review may be an adverse effect determination. If this happens, applicants should remember that a Section 106 assessment of effects is based solely on the impacts on historic properties, with no consideration given to potential benefits to the environment, the surrounding community, costs, or similar factors. If a project is determined to have an adverse effect, it simply means a few more steps are necessary to proceed. The first two steps are to look at all alternatives that would avoid or minimize the impact to historic properties, such as maintaining the dam as-is, partial versus full breach, etc. If, after all alternatives have been explored that avoid or minimize the adverse impact of partial or full demolition and data-driven explanations for ruling out these alternatives have

been provided, with SHPO's and other consulting parties' acceptance, then the third step is mitigation. Mitigation must benefit preservation/history and have some linkage with the impacted area. Once mitigation is agreed to by all parties and a legally-binding Memorandum of Agreement or Permit Special Condition is executed, then the project can continue concurrently with the mitigation.

The Advisory Council on Historic Preservation (ACHP) is charged with ensuring federal agency regulatory compliance with the NHPA. Although ACHP is usually not involved with the Section 106 process it will occasionally become involved if the project is precedent-setting or very complicated or if it engenders numerous conflicting viewpoints, or if the applicant is asked to involve one of the required consulting parties. If the project is determined to have an adverse effect, the federal agency or their delegate is required to ask the ACHP if they want to be involved in the resolution of adverse effects, regardless of whether it has been involved in the past. Most of the time, the agency does not get involved unless one of the above circumstances occurs. More information specific to Georgia can be found on the SHPO's webpage. If applicants have additional questions, they may also reach out to the Georgia SHPO by reviewing the contact list. (see Environmental Review).

### **STEP 4: PLANNING AND DESIGN OF THE PROJECT**

Once the information outlined in steps 1, 2, and 3 of this Handbook has been gathered, it is time to begin the planning and design phase. Project planning and design are case-specific and can be relatively simple or, in the case of larger projects, involve multiple intermediate steps including a feasibility study, a conceptual design, and a preliminary design, before the final design is completed. Dam removal planning and design is not a linear process. It is the job of the owner's project manager to coordinate multiple work streams in synchrony through the planning, design and implementation phases.

#### Section 4.1 Identifying Consultants

Dam removal, as a practice, is relatively new in Georgia. One of the most critical tasks in the dam removal process is the selection of qualified consultant to lead the project. Environmental, economic, ecological, engineering, social and legal complexities require a multidisciplinary approach. An effective lead consultant can assist project partners in building a successful team. Dam removal projects depend on effective communication between project partners, regulators and consultants. For this reason, taking the time to carefully research the dam, the river and surrounding landscape, and the basic regulatory process prior to selecting consultants is essential. If the project manager or dam owner is uncertain of how to find qualified professionals, one option is to consult the Georgia Safe Dams program's list of Engineers of Record, which is updated regularly. Note that this list must be used if the dam is regulated under the Georgia Safe Dams Program. For additional information, see the GA ACT webpage.

#### Section 4.2 Identifying Relevant Stakeholders

As a project plan is being developed, it will be important to consider those outside the core project partners that will be affected by the dam removal. Careful consideration of values and opinions of relevant stakeholders can help to minimize conflict as information about the project becomes public. From the outset of the planning process, the project team should develop a clear outreach plan to share with stakeholders on the purpose and intent of the removal. The facts related to benefits of dam removal including in this Handbook may provide helpful information during the outreach portion of the project.

# Section 4.3 Evaluation of Project Alternatives

As information from all relevant stakeholders is assimilated by the project team, it is important to remember that the final plan will be evaluated by multiple regulatory agencies. The final design may include a comprehensive evaluation of designs utilizing the information gathered to assess impacts to resources and costs and benefits that may result in modification of the original planned design.

This process should begin with careful consideration of all potential effects of removing the dam. Much of the information required has already been described in previous sections of this handbook. Beyond information gathered for the permitting process, this step should consider all stakeholders involved. Examples of the types of effects to consider are:

- Ecological Effects (Please refer to Step 2.0 Basic Description of the Resource, Mapping & Surveys of this document for details)
- Economic Considerations
  - Dam owner costs and benefits
  - Societal costs and benefits
  - Recreational costs and benefits
  - Environmental costs and benefits
  - Property value considerations
  - Costs/risks associated with dam
  - Availability of funding for dam repair or removal
- Societal Issues
  - Community relationship to the river
  - Services provided by the dam
  - Community sentiment towards the river and the dam and dam removal process.
  - Historical significance of the dam
  - Recreational safety
- Technical/Engineering Issues
  - Feasibility of repairing and maintaining the existing structure
  - Feasibility and design of dam removal

Ultimately, this evaluation of project alternatives should describe a process acceptable to all relevant stakeholders.

#### Section 4.4 Stages of Project Design

For very simple, straightforward projects the information gathered in steps 1, 2 and 3 of this Handbook plus the results of project alternatives analysis may be sufficient to develop a final project design for the purposes of permit application. This determination should be made by the lead consultant for the project. For more complex projects, and in order to ensure successful implementation subsequent to permitting, additional stages will likely be required. These intermediate stages may include the following.

#### Section 4.4.1 Feasibility Studies

If problems or unanswered questions arise during the early stages of information gathering and project planning, a more detailed feasibility study may be warranted. This study may be conducted by project

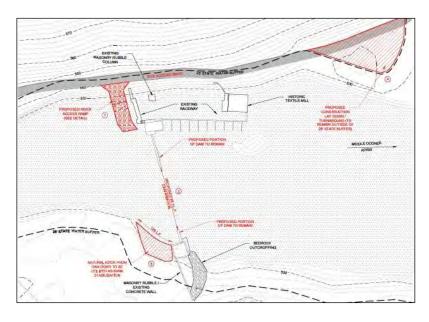

partners with appropriate skills, by consultants, or a combination of the two. Feasibility studies often involve additional data collection including economic, technical, legal and logistical considerations. The goal of this process is to provide the best available solution in order to achieve all identified project goals.

# Section 4.4.2 Conceptual Design

Once the project team feels an optimal approach to meeting their goals has been identified, it is time to prepare a concept-level description of planned work. This concept-level description may be referred to as a "10% design" and will include preliminary drawings or other materials that can be used to articulate the overall design to key stakeholders, including regulators, so they can provide feedback before details are finalized.

### Section 4.4.3 Preliminary Design

After any questions or concerns raised by key stakeholders and regulatory agencies have been addressed, a more detailed plan, sometimes referred to as a "30% design" can be prepared.

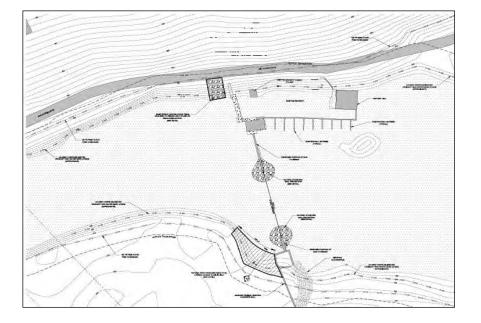

Preliminary or proposed conceptual design drawing for White Dam, Athens, GA

# Section 4.4.4 Final Design

The last stage of the design phase is the preparation of construction documents and specifications. These documents convey all project design requirements through detailed drawings and specifications. All required machinery, equipment, and material specifications must be clearly indicated. A technical memorandum describing the analysis process and approach will also be included. Final design may include the following:

- Design drawings showing plans for dam removal, sediment management, and channel restoration plans as necessary to reflect the project complexity. Plan sheets typically include base maps and drawings of:
  - Existing site conditions
  - Staging areas and access

- o Removal plan
- Dewatering plan (sometimes completed by the contractor)
- Delineation of resource areas
- Proposed plan view
- Proposed cross sections
- Proposed longitudinal profile
- o Erosion prevention and sediment control practices
- Infrastructure replacement/protection
- Habitat feature installation schematics

Final design drawing submitted with permit application, White Dam, Athens, GA

- Project specifications providing details on the construction work that will be completed. For very simple projects, specifications may be included directly on the design plans. Typically, specifications detail the following:
  - Timeline for construction and restoration
  - Construction equipment needs
  - Material specifications and quantities
  - Project sequencing
  - Staging area treatment
  - Site access route treatment
  - Dewatering
  - Other site-specific details, i.e, planting plans, traffic control, infrastructure protection, etc.

#### Section 4.4.5 Pre-Construction Public Relations

At this stage of the project, it is very important to ensure that the community is aware of the upcoming removal and has a chance to ask questions and get information. American's River's <u>Removing Small</u> <u>Dams, A Guide for Project Managers</u> provides a good overview on this process (see Step 7).

#### Section 4.4.6 Additional Considerations

- Data collected during the preliminary design can provide the baseline for post-project monitoring if the preliminary design analysis is done with monitoring in mind. (See 'project monitoring' in Step 6: Post-Removal Actions for more information.)
- Permit Identification The lead consultant will assist the applicant in applying for the appropriate federal, state, and local permits required. Permits must be on site and available during construction.
- Technical Memorandum A Technical Memorandum, prepared to accompany all design documents submitted for permit consideration, should describe the analysis and provide a recommended approach for each issue.
- Cost Estimate The design team, with the help of the lead consultant, should develop cost estimates to bring the recommended approach to completion, including costs of permitting and construction.

The following table provides a list of tasks for a relatively complex project. Not all of these tasks may be necessary for any given project, and some additional tasks may be needed depending on the project.

# **EXAMPLE: PROJECT TASKS FOR A WORK PLAN**

- Υ Hire Project Engineer
- Y Create Scope of Work (SOW) and timeline for all project staff and/or contractors
- $\Upsilon$  Create Education and Outreach strategy
- $\Upsilon$  Conduct outreach to affected stakeholders
- Y On-going communication with your group (watershed council, federal/state partners, other)
- $\Upsilon$  Participate in public meetings with affected stakeholders
- $\Upsilon\,$  Build Technical Team and facilitate Technical Team meetings
- Υ Collect background site data
- $\Upsilon$  On-going communication with a gency staff
- Y Participate in Technical Team meetings; incorporate feedback into project design & timeline
- $\Upsilon$  Create a hydrological model of the system
- Υ Conduct topographic and bathymetric site survey (including longitudinal profile)
- Υ Collect current discharge data
- Υ Conduct pebble counts
- Υ Conduct sediment sampling
- $\Upsilon$  Conduct geomorphic survey
- $\Upsilon$  Collect and analyze discharge data from historic records.
- Y Create reports, maps and alternatives analysis of site options for maintaining or removing dam
- $\Upsilon$  Develop conceptual design for preferred alternative
- $\Upsilon$  Develop preferred alternative to the 60% design level to submit for permits
- Y Prepare permit applications and all necessary accompanying data
- $\Upsilon$  Prepare 90% design for final permit agency review
- Υ Prepare 100% design
- $\Upsilon$  Prepare bid and specification documents and distribute to potential contractors
- Υ Manage bid process to select project contractors(s) for project implementation
- $\Upsilon$  Provide construction oversight
- Υ Provide any required site monitoring during construction (typically water quality sampling)
- $\Upsilon$  Prepare as-builts upon project completion
- Υ Prepare final reports for funding agencies
- Υ Conduct archaeology survey (per SHPO standards)

Modified based on Hoffert-Hay, D. 2008. *Small Dam Removal in Oregon: A Guide for Project Managers*. Oregon Watershed Enhancement Board.

#### **STEP 5: IMPLEMENTATION AND CONSTRUCTION**

As dam removal is a relatively new form of aquatic restoration in Georgia, even experienced consultants and engineers may not be familiar with the associated logistical challenges. For this reason, successful implementation of a dam removal project depends on linking the contractor who will actually remove the structure with the consulting team designing the project to be certain that what is "on paper" can actually be implemented on the ground and in the water. This is important in terms of human safety, habitat considerations, cost and timing.

Once an initial conceptual design is available, a site visit should be scheduled with the Corps project manager, consulting engineer and the contractor who will implement the final plan. This will allow all parties to talk through the design and make changes as needed. Additional site visits will likely be required throughout the planning and design process.

While the final approach for removing the structure will have been documented during the project planning and design phase, some issues may have a significant effect on implementation. These include:

- The condition of the dam and associated structures in terms of safety concerns including public access to the site
- Access to the site by contractors for construction equipment, materials and staging areas
- Site limitations, such as utilities or topographic constraints

#### **Section 5.1: Project Deconstruction**

Once all of the work on planning and design has been completed, and all necessary permits have been obtained, removal can be scheduled. The physical work of removal will likely take a relatively short time in comparison to all other stages of a project.

The project manager should work closely with the consulting team to select an experienced contractor to do the physical work of removal or deconstruction. Construction may be bid out to qualified contractors, and it is important to ensure that all contractors are licensed, bonded, and insured. In some cases, agency programs may provide qualified personnel and the appropriate equipment to complete some or all work (see inset on the US FWS National Fish Passage Program, pg. 36). During construction, the project manager and other members of the design team should always be present on-site to oversee the process. For all dam removal projects, unforeseen circumstances may arise, requiring rapid decision-making and response.

If site monitoring is required by the permit (e.g., water quality, biological, geomorphological monitoring, etc.), it should be done by professionally qualified personnel. Site monitoring may help to demonstrate the ecological impact of the removal. Even if monitoring is not required by the project permit, video and photographic documentation of all critical steps of the removal process are recommended to document and help communicate the outcome of the project to all stakeholders.

Once removal is initiated, it may become necessary to deviate from the original project design. If this occurs, notes should be made on the design drawings indicating all modifications.

# U.S. Fish and Wildlife Service National Fish Passage Program and the Southeast Aquatic Restoration Team

The U.S. Fish and Wildlife Service, National Fish Passage Program (NFPP) is a federal program which provides financial and technical assistance to reconnect aquatic habitats through the removal of barriers. The NFPP works in partnership with state and federal agencies, non-government organizations, universities, and tribes. The NFPP focuses solely on issues surrounding aquatic barriers (including obsolete dams) and restoration of waterway connectivity. This nationwide program includes the Southeast Aquatic Restoration Team, who have worked successfully with stakeholder groups in a number of states including Georgia. The members of this team are highly experienced equipment operators who have successfully removed dams of all sizes.

Tripp Boltin US FWS - South Atlantic-Gulf and Mississippi Basin Fish Passage Coordinator walter\_boltin@fws.gov

## Section 5.2 Public relations during construction

A dam removal is an uncommon event and will likely get a lot of attention. It is important to plan to have sufficient personnel prepared to handle visitors to the site and even inquiries from local media. While this is an excellent opportunity to tell your project's story, everyone involved must exercise all appropriate safety precautions. Prior to initiating construction, the project manager should delegate someone with detailed knowledge of the overall plan to interact with visitors. Consult the contractors and equipment operation crew and establish a designating viewing zone a safe distance from the active site.

Prior to removal, a viewing zone for visitors should be established a safe distance from the active site

### **STEP 6: POST REMOVAL ACTIONS**

Monitoring project results is an important step in the dam removal process. First, a project evaluation should be completed to determine if the engineering design was constructed properly and to ensure that the project is performing successfully in terms of infrastructure and public safety. If required by the permit, environmental monitoring may be needed to demonstrate that habitat restoration goals were met.

### **Section 6.1 Project Evaluation**

If required by the permit or of interest to the project manager or dam owner, the project team should plan to complete regular inspections of the removal site. They may seek the assistance of the lead consultant in developing a checklist of issues to inspect periodically. The checklist might include visual or quantitative assessments of vegetation growth, erosion and sediment transport, and scour around remaining infrastructure, such as abutments.

### Section 6.2 Environmental Monitoring

If required, environmental monitoring of dam removal projects will involve evaluating changes in ecological, hydrologic, and geomorphic parameters to assess project success. If a monitoring plan was

developed during the project development phase, it will have established pre-project baseline conditions. Trained personnel from universities, environmental consulting firms, or scientific staff from various non-profits can complete environmental post-construction monitoring activities to evaluate how conditions have changed. In some cases, state or federal agencies can provide assistance with project monitoring, such as by evaluating fish populations before and after dam removal.

The U.S. National Oceanic and Atmospheric Administration (NOAA), in cooperation with various partners, has prepared useful monitoring-related resources including the <u>Stream Barrier Removal</u> Monitoring Guide by the Gulf of Maine Council on the Marine Environment and <u>NOAA's Guide for</u> Monitoring and Evaluation for Restoration Projects.

A useful approach to post-project monitoring includes the development of fixed photo stations to photograph the site from the same location repeatedly over time. In addition, there are a number of parameters that can be monitored to track the ecological success of a project. Broad categories include:

- Ecological Response
  - Evaluate changes in fish, benthic macroinvertebrate, and other aquatic species communities.
  - Evaluate vegetation regrowth on exposed lands, quantifying both native and invasive exotic species abundance and distribution.
- River Channel Response
  - Evaluate sediment transport and deposition, erosion, and habitat structure by surveying channel morphology and analyzing bed material samples.
- Water Quality Response
  - Evaluate changes in water quality, including such parameters as water temperature, dissolved oxygen, and turbidity.
- Hydraulic Response
  - Evaluate changes in flow velocities that may impact aquatic species movement and recreational boating safety in the river.

Drone imagery can be very useful in monitoring changes in river morphology after dam removal.

Finally, once the removal is complete, report it to <u>American Rivers</u> to add it to the database and get a dot on the national tracking map!

## LOOKING AHEAD

The GA ACT was created to support and encourage the removal of obsolete dams in Georgia for all of the benefits it provides to dam owners, recreational users, fish passage, water quality, state and local economies and public safety. The GA ACT hopes that the links, contacts and information provided in this Handbook will greatly assist dam owners or project managers to prepare complete applications and navigate the regulatory process.

As the practice of dam removal continues to grow in Georgia, the GA ACT will provide updates to the Handbook and share the community's experiences and lessons learned on the <u>ga-act.org</u> webpage. The GA ACT looks forward to tracking the number of dams removed and the river miles restored in Georgia, restoring the beautiful natural heritage of the State.

Please visit the webpage, ask questions, leave comments and learn how you can help to restore rivers and streams in Georgia.

## **CASE STUDY 1**

### City Mills and Eagle & Phenix: Two Large, Historical Dams Originally Built for Mills Removed

In 2012 and 2013, the City Mills and Eagle & Phenix run-of river dams became the first major dams to be intentionally breached and partially removed in Georgia and Alabama.

In the late 1980s, residents of the Columbus, Georgia area started discussing the possibility of breaching or fully removing two Chattahoochee River dams dating to the nineteenth century. By the early 2000s, an initiative shepherded by Uptown Columbus, Inc. in collaboration with Phenix City, Alabama, the U.S. Army Corps of Engineers, other stakeholders, and their contractors launched an ecological restoration and recreational enhancement project in the Chattahoochee River Fall Line region.

The City Mills dam site is located approximately 1.3 miles downstream of Georgia Power's existing North Highlands Dam, and the Eagle & Phenix site is an additional 0.75 miles downstream from City Mills. Portions of the dams and the associated power houses remain in place on the river's banks. Both dam complexes contributed to the National Register of Historic Places (NRHP)-listed Columbus Historic Riverfront Industrial District National Historic Landmark status. In 2018, the Eagle & Phenix power house opened as a repurposed special event space, and the City Mills property is anticipated to be converted into commercial and residential properties.

After spending over \$24 million in public and private funds, the breaching and partial removal of the two structures opened up 2.3 miles of river and previously inundated shoals that were further altered to create the nation's longest urban, artificial whitewater paddling course. Between opening on Memorial Day 2013 and mid-2017, more than 100,000 people reportedly floated down the river. Combined with redevelopment of land on both sides of the Chattahoochee River including 22 miles of trails, playgrounds, a splash-pad, amphitheaters, and a zip-line attraction in downtown Columbus and Phenix City, the whitewater course is said to have contributed to the growth in the number restaurants, businesses, and residences, and a 45 percent increase in gross receipts for the local economy.

### **Step 1: Information on the Dams.**

Two sources provide information on the physical, human, and cultural history of dams. The first is maintained by Uptown Columbus: "Investigations into the Historic Mill Dams on the Chattahoochee River." A second source is the "Historical & Cultural Resources" section (Appendix C) of the U.S. Army Corps of Engineers Section 206 Environmental Restoration Report: Aquatic Ecosystem Restoration of the Chattahoochee River at Columbus, Georgia and Phenix City, Alabama (September 2004). Prior to breaching and partial removal, the City Mills dam

may have been the oldest on the Chattahoochee River. The first dam at the site was constructed in 1828. The original wood crib dam was replaced with a masonry dam immediately downstream in 1871, which was rebuilt in 1883. The dams provided hydropower for grist and flour mills. The approximately 10 foot-tall and 850 foot-long dam that was breached in 2013 was built between 1904 and 1907.

The Eagle & Phenix dam was constructed in 1844. Like the City Mills dam, the original dam was a wood crib structure that eventually transformed into a 17 foot tall and 900 foot-long masonry barrier. The Eagle & Phenix Mills shared the dam site and hydropower with Muscogee Mills. Over the years the dam and associated structures were reconfigured on at least four occasions. In 1880, the Eagle & Phenix Mills installed electrical generation equipment in the powerhouse and was one of

the first sites in Columbus to use electricity for lighting. The powerhouse supplied electricity to an operational textile mill until 2002 when a lightning strike and fire damaged the facility. Subsequently the mill ceased operations. In 2003, W.C. Bradley Company acquired the Eagle & Phenix dam and powerhouse.

### Step 2: Information Relating to the Stream or River

The best source of information for preconstruction and planning for hydrology, stream flow, habitat, and significant species can be found in the U.S. Army Corps of Engineers *Section 206 Environmental Restoration Report: Aquatic Ecosystem Restoration of the Chattahoochee River at Columbus, Georgia and Phenix City, Alabama* (September 2004). This report contains the Environmental Assessment and Finding of No Significant Impact statement, a full discussion of alternatives, the U.S. Fish and Wildlife Coordination Act Report, and other related documents.

### Step 3: The Regulatory Process to Obtain the Approval for Removal in Georgia and Alabama

In 2012 and 2013, the City Mills and Eagle & Phenix run-of-river dams became the first major dams to be removed in Georgia. The dams, mills, and associated properties are National Historical Landmarks (NHL) located in the Columbus Riverfront Industrial District that was listed with the National Register of Historical Places in 1978.

As an aquatic restoration project, these barrier removals occurred under the terms of a single individual U.S. Clean Water Act Section 404 permit. In September 2004, the U.S. Army Corps of Engineers Mobile District issued an Environmental Assessment and Finding of No Significant Impact. In 2010, under Section 106, the project was determined to have an adverse effect on the historically significant NHL. The resolution of adverse effect process (avoidance, minimization, and mitigation) resulted in mitigation including archival recordation of the dams, archaeological investigation, historic narratives, educational outreach documents, preservation of portions of the dams nearest the banks, and utilization of removed portions of the dams in historic exhibits. In March 2011, the Georgia Environmental Protection Division issued a U.S. Clean Water Act Section 401 Water Quality Certification and a Stream Buffer Variance (Georgia Erosion and Sedimentation Control Act). This was followed by the issuance of a Section 404 Permit in May 2011.

Both dams were independently owned, and regulated by the Federal Energy Regulatory Commission (FERC). The City Mills Dam (P-8519) was exempt from FERC licensing because the project produced less than 10 megawatts but was still mandated to meet some FERC requirements. The mill and dam properties were transferred from private ownership to Uptown Columbus; the mill is currently in private ownership. The Eagle & Phenix Dam (P-2655) license was held by Consolidated Hydro Southeast Energy, Inc. until the dam and powerhouse were acquired by W.C. Bradley Company in 2003 (the FERC

license expired in 2009); the dam property was transferred to Uptown Columbus prior to removal. In 2011, FERC approved Uptown Columbus' applications for surrender of both licenses, and then Uptown Columbus initiated the decommissioning process.

According to the Corps, in 2004 it was assumed that the shallow reservoir pools behind the two dams did not contain "significant quantities of sediments" in need of excavation. While some sediment was expected to be removed, the Corps proposed "limited grassing of approximately 25 acres of the newly exposed pool bottoms" to reduce erosion problems and the planting of native bottomland hardwood tree species.

## **Step 4: Plan and Design the Project**

Not unlike other Fall Line rivers in Georgia, this 2.3 mile section of the Chattahoochee River was inundated for over 170 years. The Chattahoochee River from the Corps-operated West Point Lake's headwaters to Lake Seminole was 97 percent impounded prior to restoration. The goal of the dam removal project was to restore a few miles of a unique Fall Line section of river to a free-flowing condition to benefit state threatened species and species of concern. The plan included breaches in both dams, construction of rock 'fish' ramps to improve aquatic passage, rock weirs to ensure a back water refuge above the Eagle & Phenix dam, modification of five combined sewer overflow outlets to ensure water quality, and a constructed whitewater boating course.

Project planners and designers also had to coordinate with the Georgia Power Co. and the Corps. Georgia Power's North Highlands Dam and the Corps' West Point Dam control the amount, timing, and duration of flows of water on this section of the Chattahoochee River. Flows can vary between 800 cubic feet per second (cfs) to more than 10,000 cfs depending on upstream generation and release schedules to meet flood control, navigation, electrical generation, and other Corps project needs throughout the Chattahoochee River basin. Additionally, Georgia Power had to build a new weir just below North Highlands to maintain a pool at the base of the dam after City Mills was removed; North Highlands was built assuming that the pool would always be there, and if the base of the dam had been dewatered, the turbines would have become unstable. The weir remains in operation today to maintain the pool below the dam.

The restoration project was led by Uptown Columbus, Inc. Permitting and regulatory consulting was provided by CH2M Hill. The whitewater recreation elements were designed and engineered by the McLaughlin Whitewater Design Group. They conducted extensive stream bed mapping (bathymetric survey) and hydraulics modeling (including construction of a physical model) to understand how the river flowed under different conditions, and how those flows would meet both ecological restoration and recreation goals. Batson-Cook Construction performed the work, including the breeching of the dams and constructing the whitewater course elements: two channels, multiple water diversion elements, and an adjustable hydraulic diversion called Wave Shaper.

The \$24 million project was financed by public and private funds. Over half of the money—\$13.8 million—was provide by individual, corporate, and foundation donors. The remaining \$10.6 million in public funding came from the city of Columbus (\$5 million), the U.S. Army Corps of Engineers (\$5 million), and the National Oceanic and Atmospheric Administration (\$600,000).

## **Step 5: Project Implementation/Dam Deconstruction**

The breaching and partial removal of both dams was phased. The Eagle & Phenix was breached in 2012 and City Mills was breached one year later. To dewater the working areas, water was passed through each powerhouse. Physical removal was accomplished by controlled explosive detonation and mechanical excavation. Rock and other debris from the dams was removed from the stream bed except for some rock that was repurposed for instream flow diversions, rock weirs, and stream bank protection.

### **Step 6: Post Removal Assessment**

A 2017 post - barrier removal assessment echoes the economic benefits stated above and indicates "the dam removal project has not been successful at restoring riverine fish" as anticipated. (Sammons, 2017) While a 2.3 mile section of the Chattahoochee River's 430 miles is now barrier free, it remains constrained by the upstream North Highlands Dam and downstream by the back waters of Walter F. George reservoir. Two old mill dams were removed, but new large artificial drops, a mechanical Wave Shaper, and two sculpted channels funnel significant volumes of water at high velocity through the whitewater course. For riverine fish, the whitewater course may have become a new barrier. According to the assessment, this barrier may not allow native river fish to move upstream through the rapids, but it may also prohibit the upstream movement of non-native species such as flathead catfish. The case of one riverine fish species—the Shoal Bass—is more perplexing. Prior to removal, isolated Shoal Bass communities lived in each impoundment. A primary justification for the ecological restoration project was that barrier removal would facilitate the development of a continuous population of shoal bass. According to the assessment, the opposite may have happened and shoal bass appear to disappear from this reach for unknown reasons.

Like most barrier breaching and removal projects, including others referenced in this Handbook, sediment did move downstream as demonstrated by "large vegetated islands" that "formed in mid channel and on the Alabama side of the river after the dams were breached."

Additional "restoration projects continue, including removal of invasive plants and planting" of shoal spider lilies.

## CASE STUDY 2

### Three Small, Non-regulated Earthen Dams to Be Removed by The Nature Conservancy

#### Step 1: Research Information on the Dam

The Nature Conservancy is removing three earthen dams on their own land in Marion County, just east of Fort Benning Army Base. There is no official record of the history or purpose of the dams. The following information has been gathered from aerial imagery and observational surveys. All three of the dams were likely built for recreational hunting, fishing and possibly agricultural water supply. The dams range in size between 280-475 feet wide and 9-20 feet tall, and they have all been naturally breached with their impoundments mostly drained. Two of the dams are overgrown with vegetation and they are all eroding sediment into their respective stream channels. The Nature Conservancy's land as well as most of the adjacent tracts are used for forest management, including active timber operations and wildlife related recreation via hunting leases. There is no major public or private infrastructure that would potentially be impacted by the dam removal projects, no hazardous material, and no known historical significance of the dams

A kml file containing the tract boundaries, barrier locations, and impoundment footprints can be downloaded from: http://bit.ly/2JwuEO2

Figure 1: The two lower dams of the three will be removed on the Hopkins Tract

#### Step 2: Research Information Relating to the Stream or River

The original impoundments on the Hopkins Tract were 2.95 acres for the middle dam and 2.74 acres for the lower dam. The Little Pine Knot impoundment was 5.31 acres. All three impoundments are now highly variable due to breaching. The streams have not been assessed for water quality; however, they all

Figure 2. Little Pine Knot Dam will be removed.

exhibit bank instability and erosion, causing a significant amount of sedimentation. Removing the dams will restore natural stream habitat for fish and crayfish, as well as reconnect existing habitat both downstream and upstream of the sites. There are no endangered species predicted to be impacted by the dam removals and there are no known invasive species in the area that the dam removals would release. It is unlikely that the sediment behind the dams is contaminated due to the fact that timber harvest has been the historical land use in the surrounding area. The land is currently maintained for native forest restoration and private hunting through a lease. It is not open for public recreation. Hunters seeking waterfowl that previously frequented the impoundments may experience a shift in the types of birds attracted to the area. However, conservation and restoration goals take precedence over hunting opportunities on these properties.

Figure 3: Breach of lowest dam on Hopkins Tract, looking upstream

### **Step 3: Know and Understand the Regulatory Process to Obtain a Permit for Removal in Georgia**

The Pre-Construction Notices and permit applications were submitted to the U.S. Army Corps of Engineers on July 31, 2019. Both projects were conducted under the *NWP 27 for Aquatic Habitat Restoration, Establishment, and Enhancement Activities.* The Hopkins Tract project could have qualified under *NWP 13 for Bank Stabilization*, but due to The Nature Conservancy's commitment to ecological monitoring, the restoration permit ended up better fitting the project description. Permit applications for the projects were simultaneously submitted to the Georgia Environmental Protection Division for Stream Buffer Variances.

More information will be available once The Nature Conservancy receives responses from the U.S. Army Corps of Engineers and Georgia Environmental Protection Division.

## Step 4: Plan and Design the Project

The purpose of these dam removals is to restore aquatic connectivity in the watersheds, to reduce the amount of sediment input from the unconsolidated fill within the structures, and to restore hydrologic function to the tributaries and their natural floodplain. Two of the dam removals will focus on the widening and flattening of a notch area from each structure where they have already been breached and then stabilization of the remaining fill to prevent erosion. The third dam will be modified by plugging the existing breach, creating a new notch on another part of the structure, and creating a new stream channel for 500-1000ft downstream of the dam using Natural Channel Design or another accepted method. This approach is necessary due to the significant elevation difference between the existing impoundment and the downstream stream channel. Local materials and appropriate, native riparian vegetation will be used to stabilize the channel following Natural Channel Design principles.

Figure 4: Standing on the top of the breached middle dam looking down (~10 ft tall) on Hopkins Tract

Ecological and geomorphic monitoring will be conducted at both sites pre- and post- restoration by a group of faculty and students in the Earth and Space Science Department at Columbus State University.

## **Step 5: Project Implementation/Dam Deconstruction**

More information will be available as the projects unfold.

## **Step 6: Post Removal Actions**

The Nature Conservancy plans to share these projects on American River's interactive map that shows all of the U.S. dams removed since 1912.

Figure 5: Erosion at Little Pine Knot Dam face

## **CASE STUDY 3**

## White Dam: A Moderate-sized Historical Mill Dam Removed

In 2018, the White Dam, owned by the University of Georgia, became the first run-of-river dam in Georgia to be intentionally breached and partially removed solely for the purpose of habitat restoration.

In October 2015 the first dam removal workshop in Georgia was held. It was hosted by the Nature Conservancy (TNC), Southeast Aquatic Resources Partnership (SARP), the University of Georgia (UGA) Warnell School of Forestry and Natural Resources and American Rivers. A number of aquatic conservation professionals were present, including federal personnel from the US Fish and Wildlife Service, USDA Natural Resources Conservation Service and US EPA. State agencies represented included the GA DNR Wildlife Resources Division, Fisheries and Non-game sections, GA DNR Environmental Protection Division, and GA EPD Safe Dams Program. Non-governmental organizations in addition to those hosting included the Georgia River Network, Upper Oconee Watershed Network and others.

The workshop emphasized dam removal as a form of river restoration in the Southeast. In addition to formal presentations, this workshop provided a unique opportunity for all stakeholders to have conversations about the many and varied aspects of the process of dam removal.

### Step 1: Information on the Dam.

Unfortunately, historical information about White Dam was difficult to acquire, incomplete and often contradictory. The primary sources of historical information available on the White Dam were records kept by Warnell and a master's thesis entitled "Holding Back Time: How Are Georgia's Historic Dams Unique Resources?" published in 2012.

John White, and his wife Janet Richards, natives of County Antrim, Ireland came to Athens, GA in 1837. Mr. White, a textile expert, took over management of the Georgia Manufacturing Company cotton mill, located on the Oconee River in Clarke County. This mill, built in 1827, was among the first cotton mills in Georgia. Mr. White's son, John Richards White, born in 1847, eventually assumed his father's management position at the company, building a new textile mill as well as the current White Dam.

White Dam is located on the Middle Oconee River just upstream of the confluence with the North Oconee River adjacent to Whitehall Forest (figure 1). The dam (figure 2)

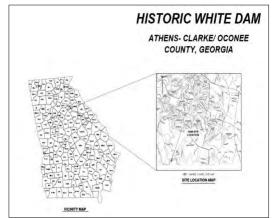

Figure 1: Site location map

was constructed between 1912 and 1913. John Richards White was among the pioneers utilizing the new technology of electricity, which freed factories from riverside sites. The hydroelectric power plant installation for the dam (figure 3) was completed by 1915 and was fully operational by 1916, according to a plat map of the area produced in May 1916 (figure 4). This power plant supplied electricity to the Whitehall Mills, including a yarn mill and a cotton mill located on Whitehall Road near the intersection with the Central Georgia Railroad lines, which were used to transport raw materials and finished products.

Figure 2: The White Dam

The Whitehall Mills and Electric Plant were sold to the Oconee Textile Company in 1937, then to Fickett Cotton Mills, Inc. in 1938. Modifications to the original plant occurred around 1940, including raising the

Figure 3: Hydroelectric power plant for the White Dam

dam level by several feet, moving the powerhouse a short distance downstream, and reinstalling the turbine at the end of a longer raceway. The plant remained in operation until the early 1950's, at which time the Whitehall Mills began purchasing all electrical power through the Georgia Power Company.

The dam and power plant were listed as structure number 68 in a Georgia state architectural survey conducted by Patricia Cooper in 1973. Cooper described the dam as being granite faced with concrete, and with a probable rubble core. She noted that the dam was intact, and that the powerhouse still contained machinery. The Hardin family, who owned the property, donated the dam and surrounding land to the University of Georgia's School of Forest Resources in 1978. During the late 1980's, the feasibility of reactivating the

hydroelectric plant was investigated, but ultimately it was determined that the project lacked economic viability.

In 1992 David Cullison conducted a Georgia State historic resources survey in which the dam is assigned resource ID 2952 and described as follows: "Concrete gravity dam, with ogee section. Spillway at north end, open overflow gate near south end. Top two feet of dam constructed of stone, perhaps as an early addition. Stone foundations at either end of structure, though most of foundation is concrete. South wall of spillway is a concrete curtain wall with buttresses. Spillway is mostly dry. Stone and concrete platform at south end, possibly a foundation."

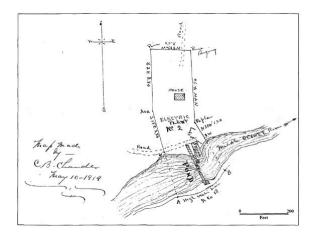

Figure 4: 1919 Plat showing White Dam and power plant

In the historical resource report Cullison assigned resource ID 2951 to the powerhouse, and described the structure as follows:

"One room, plan shape rectangular, roof type tin. Chimney material brick appears to be a later addition. Front has a large, fenced entry. Some machinery is still inside the building."

At the time of the proposed project the dam and powerhouse remain largely intact, and, from a historical perspective, the property retains integrity of location, design, materials, workmanship and association. White Dam and the associated powerhouse together constitute an important historic resource that appears eligible for listing in the National Register of Historic Places.

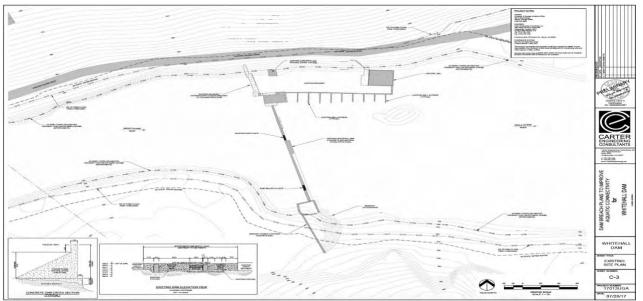

Exhibit 1: Overall Existing Site Plan, Dam Breach Plans to Improve Aquatic Connectivity for Whitehall Dam, Clarke County, Georgia

## Step 2: Information Relating to the Stream or River.

The Altamaha River Basin supports a wide array of biologically diverse ecosystems. The watershed boasts the highest documented number of rare plants, animals, and natural community occurrences in the state of Georgia. For two years prior to removal, UGA Faculty, staff and students investigated the feasibility of modifying White Dam to improve aquatic connectivity and fish passage. As part of this investigation they sought informal comment on the merit of this project from a number of interested stakeholders including the US Fish and Wildlife Service, US EPA, GA Department of Natural Resources, American Rivers and others. These investigations identified the structure as a barrier to migration of anadramous American shad *Alosa sapidissima*, and to localized migrations of resident fish species such as the imperiled Altamaha shiner *Cyprinella xaenura*. Their efforts also indicated that restoring aquatic connectivity to this section of river could result in an increase in abundance or occurrence of native unionid mussels, of which many species are imperiled.

## Step 3: The Regulatory Process to Obtain the Approval for Removal

In 2018, the White Dam became the first run-of-river dam in Georgia to be intentionally breached and partially removed solely for the purpose of habitat restoration. This removal occurred following completion of coordination between the US Army Corps of Engineers (USACE) Savannah District and other federal and state agencies as described in section 404 of the Clean Water Act. UGA was authorized to use *Nationwide Permit No. 27 for Aquatic Habitat Restoration, Establishment, and Enhancement Activities* within the Middle Oconee River (USACE permit file number SAS-2017-00086). Prior to issuance of this authorization, project planners and designers also had to coordinate removal with the Georgia Department of Natural Resources Environmental Protection Division and Athens-Clarke County.

### **Step 4: Plan and Design the Project**

The project planning team comprised University of Georgia faculty and staff. Permitting and regulatory consulting was provided by Carter Engineering Consultants of Watkinsville, GA.

During initial investigation of the structure, it was learned that White Dam had previously been identified by GA DNR and the US FWS as a potential impediment to native fish movement and aquatic connectivity. Since the cessation of power generation decades ago, the dam served no economic or floodcontrol functions but remains an in-channel obstruction. This obstruction collected a substantial pile of woody debris during high flow periods, which had to be removed regularly by UGA staff. Boaters had, on occasion, been unable to navigate the dam and their boats had become impinged on the structure, demonstrating the potential safety risk associated with the structure. The objectives of this project were to restore aquatic habitat and enhance aquatic connectivity in the area around White Dam and the nearby sections of the Middle and North forks of the Oconee River.

Because this dam would be eligible for listing on the National Register of Historic Places, and recognizing that attainment of the objectives outlined above could result in adverse impacts on the historical value of this site, the project planners evaluated the following alternatives for this project:

1. Do Nothing/Status Quo – It was recognized that this could become the very first project of its kind permitted in the Savannah District of US ACE, but that numerous dam removal and modification projects have been completed throughout the US. After evaluating conditions in the area adjacent to the structure, and consulting a number of interested stakeholders involved in projects of this type (including the US

FWS, EPA, GA DNR American Rivers and others), this alternative was rejected due to ecological concerns, as well as concerns with the safety of boaters attempting to navigate this section of the river.

2. Total Removal – While total removal of all structures (dam wall, head race and abutments on both banks of the river) associated with the dam would achieve the ecological and safety objectives, this alternative was rejected primarily because this option ignores the historical significance of the structure. Furthermore, the cost associated with total removal would have been significantly higher.

3. Construction of a by-pass channel – Project planners considered leaving the entire structure intact and digging a channel to by-pass the dam and restore ecological connectivity. This approach has been used successfully in other parts of the US. However, this alternative was rejected due to logistical problems with the topography of the riparian areas on both banks, due to concerns with hydrological stability and due to complications associated with ownership on the opposite side of the river from Whitehall Forest.

4. Modification to the existing structure - including partial removal (breach of center section of dam wall) and stabilization of remaining portions (head race, end sections of the dam wall and abutments on both banks of the river) - was evaluated. This alternative was considered most practicable because it restored hydrologic and ecological function and connectivity to the river, while retaining most of the historically significant resource. This alternative was also determined to be the most cost-effective.

**Description of most practicable alternative (partial breach):** The objective of the proposed breach was to maximize environmental and ecosystem benefits, while maintaining the structural integrity of the dam and retaining its historic value. After analyzing the hydraulic effects and consulting with a structural engineer, the best location for the proposed breach was determined to be between the existing sluice gates. The existing and proposed breach conditions of the dam and river were modeled to determine the change in hydraulic routing and what effects may occur due to the proposed breach. The modeling approach was detailed in the construction plans included in the permit application submission package. This construction alternative was selected to utilize the existing clean edges as the limits of the breach.

The approach called for the removal of all concrete and iron from a section of the center of the dam wall and retention of all native stone that was part of the original structure. This native stone was to be integrated back into the site in to stabilize the portions of the structure that remain. Project managers felt that the design represented a balance between the ecological/safety benefits of modification to the existing structure and the impact on this historically significant resource.

## **Step 5: Project Implementation/Dam Deconstruction**

The US FWS Southeast Regional Fish Habitat, Fish Passage, Maintenance and Construction Team was responsible for implementation of the construction design.

The breach plan included removing all of the concrete and natural stone wall and footing located between the two existing sluice gates. This resulted in an 88.5 linear foot open section, slightly offset to the south of the center of the dam. The remaining sections of the dam, on either side of the abutments, serve to protect the abutments from stormflow, and help maintain the structural integrity and historic value of the dam.

**Minimization of effect:** During the pre-permitting investigation process project managers consulted archaeologists, engineers, safety experts and aquatic ecologists to determine optimal placement and scale

of modification to minimize the removal of historically significant material. It was determined that an existing road could be used for all equipment staging and access required during construction. This road was already in use for regular maintenance and removal of woody debris that accumulated on the dam. A temporary river access ramp was utilized during construction.

The deconstruction of White Dam required 7 days on site from start to finish.

## Step 6: Post Removal Assessment

Archival Photo-Documentation of the existing structure, details of the proposed modification, and an environmental monitoring plan were submitted with the permit application package. USEPA Region 4 scientists assisted UGA in developing this plan. The monitoring plan included the following actions before and after removal:

- Bathymetry
- Benthic macroinvertebrate sampling
- Sediment sampling
- Water quality sampling
- Fish surveys

This monitoring is required under the terms of our NWP authorization to continue through the year 2021, but the University of Georgia intends to continue monitoring beyond that time. The removal has been reported to American Rivers and is included in the national dam removal database.
